integrity, much like a tripwire, so that unauthorized changes cannot occur (or are at least extremely unlikely to occur). We may no longer be able to afford the luxury of having firewalls placed at a fixed point in a network's infrastructure.

Firewalls of the future may need to become more like network agents, capable of distributing themselves where they are needed (and in all likelihood moving themselves when they are attacked). These firewalls should be able to govern not only traffic originating from outside the network in which they are located, but also traffic originating from within. Finally, firewalls must make the process of reading and analyzing logged data less cumbersome.

Conclusion

Despite numerous limitations, firewalls are a strong network security control measure. The proverbial smokescreen surrounding the firewalls arena is unfortunately very occlusive, so those who employ firewalls or who consider employing firewalls must learn what these devices can and cannot do. Learning what they cannot do is at least as important as learning what they can do. The proverbial smokescreen now needs to dissipate — to clear the misconceptions about firewalls that serve as an obstacle to gaining the maximum benefit from them and to establishing effective network security practices.

Physical Layer Network Security: What your LAN can do for you

D.W. Banes

The basic simplicity and ease of use of Local Area Networks (LANs) has produced an explosive growth in connectivity over the past few years so that today they have become an integral part of most business organizations. This growth has been in spite of some fundamental problems that the technology highlights in the area of security. However, these issues have almost been totally ignored in the past mainly because of a lack of understanding of the issues rather than complacency.

More reliance is being made on electronic media for our work, word processing, project management and finance all rely heavily on Personal Computers (PCs) and for network file access. A loss at any point, disk failure, network failure etc. can be catastrophic — productivity in a NetWare environment plummets if the network isn't available for even an hour. The PC itself was originally intended for private use but now is increasingly being networked. In many cases little or no procedures are put in place, so much so that a common requirement for network management is simple inventory control. Generally there is little or no understanding of exactly what equipment is present, how it is connected and who it belongs to.

One of the factors that is little understood and the main feature that allows LANs to be so simple is also its biggest security flaw. The broadcast nature of LANs means that traffic transmitted on the network must pass by all stations that are connected to the same physical LAN so that the sender has to have no knowledge of the location of
