## Abstract

In this paper we refine the notion of tree-decomposition by introducing acyclic $(R, D)$-clustering, where clusters are subsets of vertices of a graph and $R$ and $D$ are the maximum radius and the maximum diameter of these subsets. We design a routing scheme for graphs admitting induced acyclic $(R, D)$-clustering where the induced radius and the induced diameter of each cluster are at most 2. We show that, by constructing a family of special spanning trees, one can achieve a routing scheme of deviation $\Delta \leqslant 2R$ with labels of size $O(\log^3 n / \log \log n)$ bits per vertex and $O(1)$ routing protocol for these graphs. We investigate also some special graph classes admitting induced acyclic $(R, D)$-clustering with induced radius and diameter less than or equal to 2, namely, chordal bipartite, homogeneously orderable, and interval graphs. We achieve the deviation $\Delta = 1$ for interval graphs and $\Delta = 2$ for chordal bipartite and homogeneously orderable graphs.

## 1. Introduction

Routing is one of the basic tasks that a distributed network of processors must be able to perform. A *routing scheme* is a mechanism that can deliver packets of information from any node of the network to any other node. More specifically, a routing scheme is a distributed algorithm. Each processor in the network has a routing daemon (known also as a *message passing algorithm* or a *forwarding protocol*) running on it. This daemon receives packets of information and has to decide whether these packets have already reached their destination, and if not, how to forward them towards their destination.

A network can be viewed as a graph, with the vertices representing processors and the edges representing direct connections between processors. It is naturally desirable to route messages along paths that are as short as possible. Routing scheme design is a well-studied subject. For a general overview we refer the reader to [25].

Most routing schemes are *labeling schemes* that assign two kind of labels to every vertex of a graph. The first label is the *address* of the vertex, the second is a data structure called *local routing table*. These labels are assigned in such a way that at every source vertex $x$ its routing daemon can quickly decide, based on the two labels stored locally in $x$

---

and the address of any destination node *y*, whether the packet has reached its destination, and if not, to which neighbor of *x* to forward the packet.

A straightforward approach to routing is to store a *complete routing table* at each vertex of the graph, specifying for each destination *y* the first edge (or identifier of that edge, indicating the output port) along some shortest path from *x* to *y*. While this approach guarantees optimal (shortest path) routing, it is too expensive for large systems since it requires total $O(n^2 \log \delta)$ memory bits for an *n*-vertex graph with maximum degree $\delta$. Thus, for large scale communication networks, it is important to design routing schemes that produce short enough routes and have sufficiently low *memory requirements*.

Unfortunately, for every shortest path routing strategy and for all $\delta$, there is a graph of degree bounded by $\delta$ for which $\Omega(n \log \delta)$ bit routing tables are required simultaneously on $\Theta(n)$ vertices [20]. This matches the memory requirements of complete routing tables. To obtain routing schemes for general graphs that use o(*n*) of memory at each vertex, one has to abandon the requirement that packets are always delivered via shortest paths, and settle instead for the requirement that packets are routed on paths that are relatively close to shortest. The efficiency of a routing scheme is measured in terms of its additive stretch, called *deviation* (or multiplicative stretch, called *delay*), namely, the maximum surplus (or ratio) between the length of a route, produced by the scheme for a pair of vertices, and the shortest route. There is a tradeoff between the memory requirements of a routing scheme and the worst case stretch factor it guarantees. Any multiplicative *t*-stretched routing scheme must use $\Omega(\sqrt{n})$ bits for some vertices in some graphs for $t < 5$ [30], $\Omega(n)$ bits for $t < 3$ [18,14], and $\Omega(n \log n)$ bits for $t < 1.4$ [20] (see also [26] for some earlier results). These lower bounds show that it is not possible to lower memory requirements of a routing scheme for an arbitrary network if it is desirable to route messages along paths close to optimal. Therefore it is interesting, both from a theoretical and a practical view point, to look for specific routing strategies on graph families with certain topological properties.

One way of implementing such routing schemes, called *interval routing*, has been introduced in [28] and later generalized in [22]. In this special routing method, the complete routing tables are compressed by grouping the destination addresses which correspond to the same output port. Then each group is encoded as an interval, so that it is easy to check weather a destination address belongs to the group. This approach requires $O(\delta \log n)$-bit labels and $O(\log \delta)$ forwarding protocol. A graph must satisfy some topological properties in order to support interval routing, especially if one insists on paths close to optimal. Routing schemes for many graph classes were obtained by using interval routing techniques. The classical and most recent results in this field are presented in [16,17].

New routing schemes for interval graphs, circular-arc graphs and permutation graphs were presented in [11]. The design of these simple schemes uses properties of intersection models. Although this approach gives some improvement over existing earlier routing schemes, the local memory requirements increase with the degree of the vertex as in interval routing.

Graphs with regular topologies, as hypercubes, tori, rings, complete graphs, etc., have specific routing schemes using $O(\log n)$-bit labels [23]. It is interesting to investigate which other classes of graphs admit routing schemes with labels not depending on vertex degrees that route messages along near-optimal path.

A shortest path routing scheme for trees of arbitrary degree and diameter is described in [15]. It assigns each vertex of an *n*-vertex tree a $O(\log^2 n / \log \log n)$-bit label. Given the label of a source vertex and the label of a destination vertex it is possible to determine in constant time the neighbor of the source vertex that leads towards the destination. A similar result was independently obtained in [29]. These routing schemes for trees serve as a base for designing routing strategies for more general graphs. Indeed, if there is a family of spanning trees such that for each pair of vertices of a graph, there is a tree in the family containing a low-stretch path between them, then the tree routing scheme can be applied within that tree.

This approach was used in [10] to obtain a routing scheme of deviation 2 with labels of size $O(\log^3 n / \log \log n)$ bits per vertex and $O(1)$ routing protocol for chordal graphs. The scheme uses the notion of tree-decomposition introduced in [27]. There, a family of spanning trees is a collection of Breadth-First-Search trees associated with each node of the tree-decomposition. It is shown that, despite the fact that the size of the family can be $O(n)$, it is enough for each vertex to keep routing labels of only $O(\log n)$ trees and, nevertheless, for each pair of vertices, a tree containing a low-stretch path between them can be determined in constant time.

In this paper we refine the notion of tree-decomposition by introducing acyclic $(R, D)$-clustering, where clusters are subsets of vertices of a graph and $R$ and $D$ are the maximum radius and the maximum diameter, respectively, of these subsets. We develop a routing scheme for graphs admitting induced acyclic $(R, D)$-clustering where the induced radius and the induced diameter of each cluster are at most 2. We show that, by constructing a family of special spanning

trees, one can produce a routing scheme of deviation $\Delta \leqslant 2R$ with labels of size $O(\log^3 n / \log \log n)$ bits per vertex and $O(1)$ routing protocol for these graphs. Our routing strategy is inspired by and based on the work of Dourisboure and Gavoille [10]. Recently we learned that [9], too, generalizes the approach taken in [10] and obtains a routing scheme of deviation $\Delta \leqslant 2D$ with labels of size $O(D \log^3 n)$ bits per vertex and $O(\log(D \log n))$ routing protocol for the so-called tree-length $D$ graphs [9] (which turns out to be equivalent to the class of graphs admitting acyclic $(D, D)$-clustering).

We investigate some special graph classes admitting induced acyclic $(R, D)$-clustering with induced radius and diameter less than or equal to 2, namely, chordal bipartite, homogeneously orderable, and interval graphs. We achieve the deviation $\Delta = 1$ for interval graphs and $\Delta = 2$ for chordal bipartite and homogeneously orderable graphs, while the routing schemes of [9,10] produce $\Delta = 2$ for interval graphs and $\Delta = 4$ for chordal bipartite graphs. To the best of our knowledge this is the first routing scheme that is presented for homogeneously orderable graphs. Note that they include such well known families of graphs as distance-hereditary graphs, strongly chordal graphs, dually chordal graphs as well as homogeneous graphs (see [4]). Additionally, we achieve a constant time routing protocol and slightly lower memory requirements for chordal bipartite graphs (from [9] one could infer for chordal bipartite graphs a scheme with labels of size $O(\log^3 n)$ bits per vertex and $O(\log \log n)$ routing protocol).

## 2. Preliminaries

All graphs occurring in this paper are connected, finite, undirected, loopless, and without multiple edges. For a subset $S \subseteq V$ of vertices of $G$, let $G(S)$ be a subgraph of $G$ induced by $S$. By $n = |V|$ we denote the number of vertices in $G$.

The *distance* $dist_G(u, v)$ between vertices $u$ and $v$ of a graph $G = (V, E)$ is the smallest number of edges in a path connecting $u$ and $v$. The distance between a vertex $u \in V$ and a set $S$ is $dist_G(u, S) = \min_{v \in S}\{dist_G(u, v)\}$. The *radius* of a set $S$ in $G$ is $rad_G(S) = \min_{v \in S}\{\max_{u \in S}\{dist_G(v, u)\}\}$ and the *diameter* is $diam_G(S) = \max_{v,u \in S}\{dist_G(v, u)\}$. The *induced radius* of a set $S$ is $rad(S) = \min_{v \in S}\{\max_{u \in S}\{dist_{G(S)}(v, u)\}\}$ and the *induced diameter* is $diam(S) = \max_{v,u \in S}\{dist_{G(S)}(v, u)\}$. A vertex $v \in S$ such that $dist_{G(S)}(u, v) \leqslant rad(S)$ for any $u \in S$ is called a *central vertex* of $S$. Also, we denote by $N_G(v) = \{u \in V : uv \in E\}$ the *neighborhood* of a vertex $v$ in $G$ and by $N_G[v] = N_G(v) \cup \{v\}$ the *closed neighborhood* of $v$ in $G$. The *$k$th neighborhood* $N^k(v)$ of a vertex $v$ of $G$ is the set of all vertices of distance $k$ to $v$: $N_G^k(v) = \{u \in V : dist_G(u, v) = k\}$.

Our concept of acyclic $(R, D)$-clustering is a tree-decomposition introduced by Robertson and Seymour [27], except that our clusters additionally have to satisfy bounds on the radius and the diameter.

**Definition 1.** A graph $G = (V, E)$ admits an acyclic $(R, D)$-clustering if there exists a tree $T$ whose nodes $\mathscr{C} = \{C_1, C_2, \ldots, C_\kappa\}$ are subsets of $V$, called clusters, such that the following holds:

1. $\bigcup_{C \in \mathscr{C}} C = V$;
2. for any edge $uv \in E$, there exists $C \in \mathscr{C}$ such that $u, v \in C$;
3. for all $X, Y, Z \in \mathscr{C}$, if $Y$ is on the path from $X$ to $Z$ in $T$ then $X \cap Z \subseteq Y$;
4. $\max_{C \in \mathscr{C}}\{rad_G(C)\} \leqslant R$ and $\max_{C \in \mathscr{C}}\{diam_G(C)\} \leqslant D$, where $R$ and $D$ are non-negative integers.

$T$ is called a *tree-decomposition* of $G$. The value $\kappa = |\mathscr{C}|$ is called the *size of the clustering*, $R$ and $D$ are called the *radius of clustering* and the *diameter of clustering,* respectively. We assume that acyclic clustering is *reduced*, meaning that no cluster is contained in any other cluster (clearly any acyclic clustering can be reduced).

We say that a graph $G = (V, E)$ admits an *induced acyclic $(R, D)$-clustering* if $\max_{C \in \mathscr{C}}\{rad(C)\} \leqslant R$ and $\max_{C \in \mathscr{C}}\{diam(C)\} \leqslant D$, where $R$ and $D$ are non-negative integers called the *induced radius of clustering* and the *induced diameter of clustering*, respectively. An example of a graph admitting an induced acyclic (1,2)-clustering is given in Fig. 1.

We will use the following two properties of acyclic clustering.

**Lemma 1.** *Let $G$ be a graph admitting an acyclic $(R, D)$-clustering and $\mathscr{C}$ be its set of clusters. For any clusters $X, Y$ and $Z$ from $\mathscr{C}$ there exists a cluster $C \in \mathscr{C}$ such that $(X \cap Y) \cup (X \cap Z) \cup (Z \cap Y) \subseteq C$.*

**Proof.** Let $Q_{XY}$, $Q_{XZ}$, and $Q_{ZY}$ be the paths of $T$ between $X$ and $Y$, $X$ and $Z$, and $Z$ and $Y$, respectively. By condition 3 of Definition 1, any node of $Q_{XY}$ contains $X \cap Y$, any node of $Q_{XZ}$ contains $X \cap Z$, and any node of $Q_{ZY}$ contains
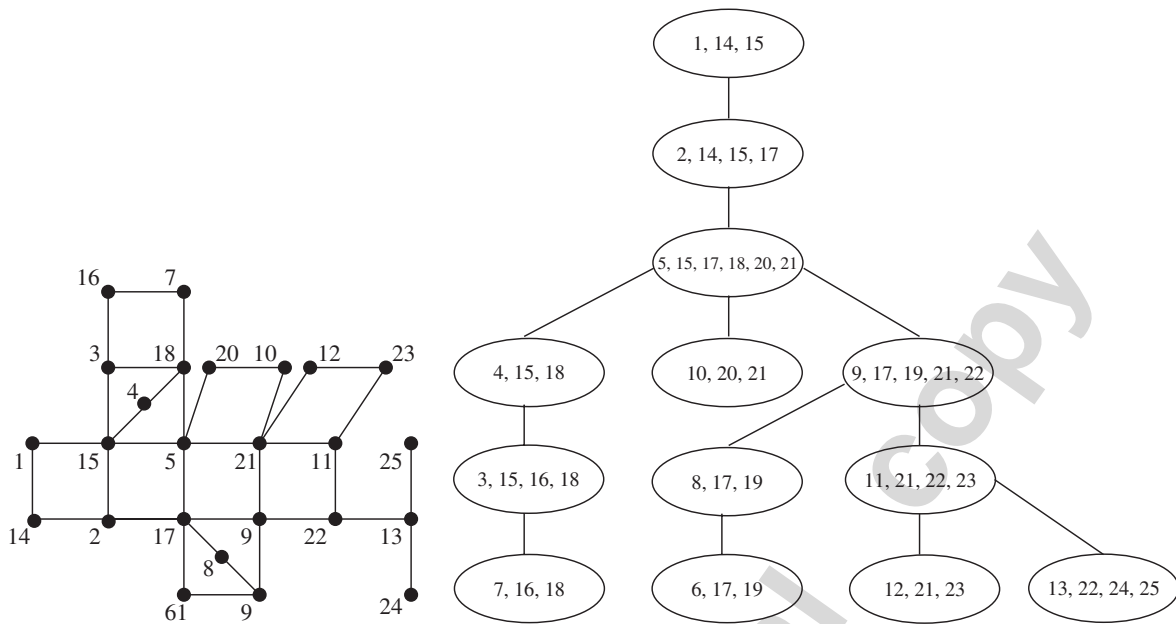

Fig. 1. A graph admitting an induced acyclic (1,2)-clustering and its tree-decomposition.

$Z \cap Y$. Since $T$ is a tree, $Q_{XY} \cap Q_{XZ} \cap Q_{YZ} \neq \emptyset$. Therefore, a cluster $C$ such that $C \in Q_{XY} \cap Q_{XZ} \cap Q_{YZ}$ exists and $C \supseteq (X \cap Y) \cup (X \cap Z) \cup (Z \cap Y)$ holds. $\quad\square$

**Corollary 1.** *Let $G$ be a graph admitting an acyclic $(R, D)$-clustering and $\mathscr{C}$ be its set of clusters. Let $\{C_0, C_1, \ldots, C_p\} \subseteq \mathscr{C}$ be a set of clusters such that $C_0 \cap C_i \neq \emptyset$ for $1 \leqslant i \leqslant p$ and there exists a vertex $x$ of $G$ such that $x \in \cap\{C_i : 1 \leqslant i \leqslant p\}$. Then there exists a cluster $C \in \mathscr{C}$ such that $\bigcup_{i=1}^{p}\{C_i \cap C_0\} \cup \{x\} \subseteq C$.*

**Proof.** First, by Lemma 1 applied to $C_0$, $C_1$, and $C_2$, there exits a cluster $C'$ containing $(C_0 \cap C_1) \cup (C_0 \cap C_2) \cup \{x\}$. Now assume, by induction, that there exists a cluster $C''$ such that $\bigcup_{i=1}^{k}\{C_i \cap C_0\} \cup \{x\} \subseteq C''$, where $k < p$. By Lemma 1 applied to $C_0$, $C''$, and $C_{k+1}$, there exists a cluster $C^*$ such that $\bigcup_{i=1}^{k+1}\{C_i \cap C_0\} \cup \{x\} \subseteq C^*$. $\quad\square$

We will need also the following well-known characterization of chordal graphs [5,7,8]. Recall that a graph is chordal if it does not contain any induced cycles of length greater than 3. A vertex $v \in V$ is simplicial in $G$ if $N_G(v)$ is a clique in $G$.

**Theorem 1** (*Buneman [5], Diestel [7], Dirac [8]*). *Let $G$ be a graph. The following statements are equivalent*:

1. *$G$ is a chordal graph.*
2. *There exists a tree-decomposition $T$ of $G$ where nodes of $T$ are the maximal cliques of $G$.*
3. *$G$ has a perfect elimination ordering, i.e., an ordering $v_1, v_2, \ldots, v_n$ of vertices of $G$ such that for any $i$, $i \in \{1, 2, \ldots, n\}$, vertex $v_i$ is simplicial in the graph $G(v_i, \ldots, v_n)$, a subgraph of $G$ induced by vertices $v_i, \ldots, v_n$.*

**Lemma 2.** *The following statements are equivalent.*

1. *A graph $G = (V, E)$ admits an acyclic $(R, D)$-clustering.*
2. *For a graph $G = (V, E)$ there exists a graph $G^+ = (V, E^+)$ such that $E \subseteq E^+$, $G^+$ is chordal, and for any maximal clique $X$ of $G^+$, $diam_G(X) \leqslant D$ and $rad_G(X) \leqslant R$.*

**Proof.** $(1) \Rightarrow (2)$ Assume that $G = (V, E)$ admits an acyclic $(R, D)$-clustering with the cluster set $\mathscr{C}$. Consider a graph $G^+ = (V, E^+)$, where $E^+ = \{uv : u, v \in V \text{ and there exists a cluster } C \in \mathscr{C} \text{ such that } u, v \in C\}$. By condition 2 of Definition 1, $E \subseteq E^+$. By construction of $G^+$, any cluster $C \in \mathscr{C}$ is a clique in $G^+$. We will show that $C$ is a

maximal clique of $G^+$ as follows. Assume that $C = \{c_1, c_2, \ldots, c_p\}$ and, by contradiction, there exists a vertex $x \in V$ such that $x \notin C$ and $C \subseteq N_{G^+}(x)$. By construction of $G^+$, there must be a cluster $C_1 \in \mathscr{C}$ such that $x, c_1 \in C_1$. Assume, by induction hypothesis, that there exists a cluster $C_k \in \mathscr{C}$ such that $x, c_1, c_2, \ldots, c_k \in C_k$, $k < p$. Since $xc_{k+1} \in E^+$, there exists a cluster $C_{k+1}$ such that $x, c_{k+1} \in C_{k+1}$. Applying Lemma 1 to $C, C_k$ and $C_{k+1}$, we obtain that there exists a cluster $C'$ such that $(C \cap C_k) \cup (C \cap C_{k+1}) \cup (C_k \cap C_{k+1}) = \{x, c_1, \ldots, c_k, c_{k+1}\} \subseteq C'$. Thus, there must exist a cluster $C_p$ such that $x, c_1, \ldots, c_p \in C_p$ and $C \subset C_p$, This contradiction with acyclic clustering being reduced establishes that any node of $T$ is a maximal clique in $G^+$. It is easy to see that $T$ is a tree-decomposition for $G^+$.

Let now $X = \{x_1, x_2, \ldots, x_p\}$ be a maximal clique of $G^+$. We will show that there exists a cluster $C \in \mathscr{C}$ such that $X = C$. By construction of $G^+$, there exists a cluster containing $x_1$ and $x_2$. Assume, by induction, that there exists a cluster $C' \in \mathscr{C}$ such that $x_1, x_2, \ldots x_k \in C'$, $k < p$. Since there are edges $x_{k+1}x_i$ in $G^+$ $(1 \leqslant i \leqslant k)$, there exist clusters $C_i$ such that $x_{k+1}, x_i \in C_i$. Notice that $x_i \in C' \cap C_i \neq \emptyset$, $1 \leqslant i \leqslant k$, and $x_{k+1} \in C_i \cap C_j$ for $1 \leqslant i \neq j \leqslant k$. By Corollary 1, there exists a cluster $C^*$ such that $\{x_1, x_2, \ldots, x_k, x_{k+1}\} \subseteq C^*$. Thus, we proved that for any maximal clique $X$ of $G^+$ there exists a cluster $C$ such that $X \subseteq C$. Taking into account that any cluster $C$ of $T$ is a maximal clique in $G^+$, we immediately have $X = C$. Thus, by Theorem 1, $G^+$ is a chordal graph.

Since the radius and the diameter of clusters in $G$ are $R$ and $D$, correspondingly, we immediately have that for any maximal clique $X$ of $G^+$, $diam_G(X) \leqslant D$ and $rad_G(X) \leqslant R$.

$(2) \Rightarrow (1)$ Since $G^+$ is chordal, by Theorem 1, there exists a tree-decomposition $T$ for $G^+$, where clusters are the maximal cliques of $G^+$. Since $G$ and $G^+$ have the same vertex set and $E \subseteq E^+$, it is easy to see that $T$ is a tree-decomposition for $G$. Since for any maximal clique $X$ of $G^+$, $diam_G(X) \leqslant D$ and $rad_G(X) \leqslant R$, we immediately conclude that $G$ admits an acyclic $(R, D)$-clustering. □

Since a chordal graph can have at most $n$ maximal cliques [21], from the proof of Lemma 2 we obtain that any acyclic $(R, D)$-clustering has at most $n$ clusters, i.e., $\kappa \leqslant n$.

## 3. Routing scheme

Let $G$ be a graph that admits an acyclic $(R, D)$-clustering and $T$ be a tree-decomposition associated with it. We assume that $T$ is rooted (say, at $C_1$). In a rooted tree $T$, $nca_T(X, Y)$ denotes the nearest common ancestor of nodes $X$ and $Y$ of $T$.

**Definition 2.** For every vertex $u$ of $G$, the ball of $u$, denoted by $B(u)$, is a node $Z$ of $T$ with minimum depth such that $u \in Z$.

It is well known that any tree $T$ with $\kappa$ nodes has a node $C$, called a *centroid* and computable in $O(\kappa)$ time, such that any maximal by inclusion subtree of $T$, not containing $C$ (i.e., any connected component of $T \backslash C$), has at most $\kappa/2$ nodes. For the tree $T$ of acyclic clustering we build a hierarchical tree $H$ recursively as follows. All nodes of $T$ are nodes in $H$. The root of $H$ is $C$, a centroid of $T$, and the children are the roots of the hierarchical trees of the connected components of $T \backslash C$. Note that the height of $H$ is $O(\log \kappa)$. The hierarchical tree for the graph in Fig. 1 is given in Fig. 2.

Let $G = (V, E)$ be a graph that admits an induced acyclic $(R, D)$-clustering with $R \leqslant 2$ and $D \leqslant 2$. Let $X$ be a node of $H$ and $u$ be a vertex of $G$ such that $u \notin X$ and $B(u)$ is a descendant of $X$ in $H$. Let $P = \{u = z_0, z_1, z_2, \ldots, z_k = x^*\}$, $x^* \in X$, be a shortest path of $G$ from $u$ to $X$.

Let $C_0 = B(u)$ and $C_i$ be the cluster closest to $C_{i-1}$ in $T$ such that $z_{i-1}, z_i \in C_i$, $1 \leqslant i \leqslant k$. Note that such clusters exist by condition 2 of Definition 1. Let $Q_i$ be the shortest path in $T$ between $C_{i-1}$ and $C_i$, $1 \leqslant i \leqslant k$. Let $Q_{k+1}$ be the shortest path in $T$ between $C_k$ and $X$. Observe that, by condition 3 of Definition 1, $z_{i-1} \in Y$ for all $Y \in Q_i$. Let $Q(P) = \bigcup_{i=1}^{k+1} Q_i$ be a path between $B(u)$ and $X$ and $Q'$ be the shortest path between $B(u)$ and $X$ in $T$. Note that, in general, $Q(P)$ is not a simple path, and $Q' \subseteq Q(P)$ for any path $P$ between $u$ and $X$.

For any two clusters $Y$ and $Z$ such that $Y, Z \in Q'$, we say that $Y$ precedes $Z$, denoted by $Y \prec Z$, if $Y$ is closer to $B(u)$ in $T$ than $Z$. We use a notation $Y \preccurlyeq Z$ if $Y \prec Z$ or $Y = Z$.

**Lemma 3.** *There exists a shortest path* $P = \{u = z_0, z_1, z_2, \ldots, z_k = x^*\}$ *between $u$ and $X$ such that $Q(P) = Q'$.*
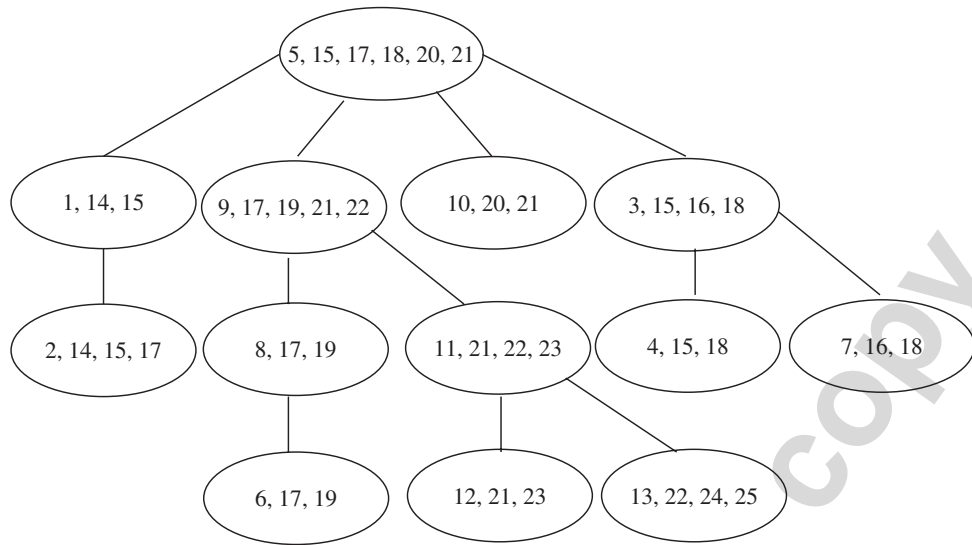

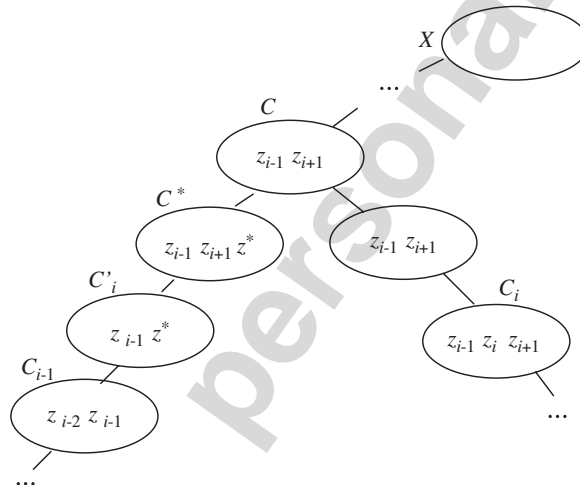

Fig. 2. A hierarchical tree $H$ for the graph in Fig. 1.

Fig. 3. Arrangements of clusters $C_{i-1}$, $C_i$, and $C'_i$ in $T$.

**Proof.** Obviously, $C_0 = B(u) \in Q'$ for any $P$. Assume, by induction, that there exists a path $P = \{z_0, z_1, z_2, \ldots, z_k\}$ between $u$ and $X$ such that $C_l \in Q'$ for $0 \leqslant l \leqslant i - 1 < k$ and $C_0 \preccurlyeq C_1 \preccurlyeq \cdots \preccurlyeq C_{i-1}$. We will show that there exists a path $P'$ between $u$ and $X$ such that $C'_l \in Q'$ for $0 \leqslant l \leqslant i$ and $C'_0 \preccurlyeq C'_1 \preccurlyeq \cdots \preccurlyeq C'_{i-1} \preccurlyeq C'_i$ as follows (see Fig. 3 for an illustration).

Let $C$ be a cluster closest to $C_i$ in $T$ such that $C \in Q'$. Since $X \in Q'$, there exists an integer $p$ such that $i < p \leqslant k + 1$ and $C \in Q_p$. Let $j > 0$ be the smallest number such that $C \in Q_{i+j}$. Notice that $z_{i+j-1} \in C$. Since $z_{i-1} \in C$ and $C$ has diameter 2, we immediately obtain that $1 \leqslant j \leqslant 2$. Note that $z_i \notin C$, otherwise $C = C_i \in Q'$, a contradiction with $C_i \notin Q'$. Thus, $j = 2$, and $C$ contains $z_{i+1}$.

We claim that $C_{i-1} \prec C$. Otherwise, $C_{i-1}$ would contain either $z_i$, meaning $C_i = C_{i-1} \in Q'$, a contradiction, or $z_q$, $q > i$, which is not possible, since $C_{i-1}$ has diameter 2 and $P$ is a shortest path.

Let $C^*$ be the cluster closest to $C_{i-1}$ in $T$ such that $z_{i+1} \in C^*$. Since $z_{i+1} \notin C_{i-1}$, we have $C_{i-1} \prec C^* \preccurlyeq C$. Since $C^*$ is on the path in $T$ between $C_{i-1}$ and $C_i$, by condition 3 of Definition 1, $z_{i-1} \in C^*$. Recall that $P$ is a shortest path and, therefore, $z_{i-1}$ and $z_{i+1}$ are not adjacent in $G$. Since $C^*$ has induced diameter 2, there exists a vertex $z^* \in C^*$ such that $z^*$ is adjacent to both $z_{i-1}$ and $z_{i+1}$.

We replace $z_i$ with $z^*$ in $P$ and obtain a new shortest path

$$P' = \{z_0, z_1, \ldots, z_{i-1}, z^*, z_{i+1}, \ldots, z_k\}.$$

Clearly, the paths $Q(P')$ and $Q(P)$ have a common prefix $\bigcup_{i=1}^{i-1} Q_i$.

```
Input:    G = (V, E);
          P = {u = z₀, z₁, ..., z_k}, a shortest path from u to X;
          Q' = {B(u) = Y₀, Y₁, ..., Y_m = X}, the shortest path in T from B(u) to X.
Output: P' = {u = z'₀, z'₁, ..., z'_k = z_k}, a Q-simple path from u to X.

set P' = ∅;
set j = 0;
for i = 1 to k − 1
 set found = 0;
 while (found = 0)
     if (z_i ∈ Y_j) then attach z_i to P' and set found = 1;
     else if (z_{i+1} ∈ Y_j) then
             choose z* from {z ∈ Y_i : z*z_{i−1}, z*z_{i+1} ∈ E};
             attach z* to P' and set found = 1;
          else set j = j + 1;
return P'.
```

Fig. 4. *Q*-simple path algorithm.

Let $C'_i$ be the cluster closest to $C_{i-1}$ such that $z_{i-1}, z^* \in C'_i$. We will prove that $C'_i \in Q'$ and $C_{i-1} \preccurlyeq C'_i$ as follows. Assume, by contradiction, that $C'_i \notin Q'$. Let $C''_i$ be the cluster closest to $C'_i$ in $T$ such that $C''_i \in Q'$. Since $C''_i$ is on the path in $T$ between $C'_i$ and $C^*$, $z^* \in C'_i$ and $z^* \in C^*$, by condition 3 of Definition 1, $z^* \in C''_i$. Similarly, since $C''_i$ is on the path in $T$ between $C'_i$ and $C_{i-1}$, $z_{i-1} \in C'_i$ and $z_{i-1} \in C_{i-1}$, by condition 3 of Definition 1, $z_{i-1} \in C''_i$. Obviously, $C''_i$ is closer to $C_{i-1}$ than $C'_i$. Since $z^*, z_{i-1} \in C''_i$, we obtain a contradiction, which proves $C'_i \in Q'$.

It remains to prove that $C_{i-1} \preccurlyeq C'_i$. Consider other possibilities. If $C_{i-2} \prec C'_i \prec C_{i-1}$, then, by condition 3 of Definition 1, $z_{i-2} \in C'_i$. In this case, $C'_i$ is the cluster containing $z_{i-2}$ and $z_{i-1}$ and closer to $C_{i-2}$ than $C_{i-1}$, a contradiction. If $C'_i \preccurlyeq C_{i-2}$, then $C'_i$ contains a vertex $z_{i-j}$, $j > 2$, which is not possible since $z^* \in C'_i$, $C'_i$ has diameter 2, and $P$ is a shortest path. Thus, $C_{i-1} \preccurlyeq C'_i$.  □

Such path $P$ is called *Q-simple* and can be constructed in $O(n^2)$ time by Algorithm *Q-simple path* presented in Fig. 4. The correctness of the algorithm follows from the proof of Lemma 3.

**Lemma 4.** *Let $P$ be a Q-simple shortest path between $u$ and $X$. Let $W = \{w \in P : B(w) \notin Q' = Q(P)\}$. Then $|W| \leqslant 3$.*

**Proof.** By Lemma 3, for each $w \in P$ there exists a cluster $C_w \in Q'$ such that $w \in C_w$. By Definition 2, for $w \in W$, $B(w) \in Q^*$ holds, where $Q^*$ is the path between $C_w$ and the root of $T$.

Clearly, $B(w) \notin Q' \cap Q^*$, otherwise $B(w) \in Q'$. Thus, $B(w)$ is on the path between $nca_T(B(u), X)$ and the root of $T$. Since $w \in C_w$, $w \in B(w)$, and $nca_T(B(u), X)$ is on the path between $C_w$ and $B(w)$, by condition 3 of Definition 1, $w \in nca_T(B(u), X)$ for all $w \in W$. Since the diameter of clusters is 2, and $P$ is a shortest path, $|P \cap nca_T(B(u), X)| \leqslant 3$. Thus, $|W| \leqslant 3$.  □

**Corollary 2.** *Let $P$ be a Q-simple shortest path from $u$ to $X$ in $G$. There are no more than 3 vertices $z$ of $P$ such that $B(z)$ is not a descendant of $X$ in $H$.*

**Proof.** Let $z$ be a vertex of $P$. Assume that $B(z) \in Q' = Q(P)$ and consider possible arrangements of nodes $X$, $B(u)$, and $B(z)$ in $H$, taking into account that $X$ is an ancestor of $B(u)$ in $H$. First, note that $B(z)$ cannot be an ancestor of $X$ in $H$, otherwise during the construction of hierarchical subtree rooted at $B(z)$, $B(u)$ and $X$ would belong to different connected components of $T \setminus \{B(z)\}$, and, therefore, $X$ could not be an ancestor of $B(u)$ in $H$. Second, if there exists a node $Y$ such that $X$ and $B(z)$ are descendants of $Y$ in $H$, then $Y \in Q'$, and, again, during the construction of hierarchical subtree rooted at $Y$, $B(u)$ and $X$ would belong to different connected components of $T \setminus \{Y\}$, and, therefore, $X$ could not be an ancestor of $B(u)$ in $H$. Thus, if $B(z) \in Q'$, then the only possible arrangement is that $B(z)$ is a descendant of $X$ in $H$. If $B(z) \notin Q'$, then, by Lemma 4, the number of such vertices $z$ is bounded by 3.  □

**Lemma 5.** *Let $u$ and $v$ be two vertices of $G$ and $X = nca_H(B(u), B(v))$, then $X$ is a separator between $u$ and $v$ in $G$.*

**Proof.** Let $P = \{u = z_0, z_1, z_2, \ldots, z_k = v\}$ be a path from $u$ to $v$ and $C_0 = B(u)$. Let $C_i$ be the cluster closest to $C_{i-1}$ in $T$ such that $z_{i-1}, z_i \in C_i$, $1 \leqslant i \leqslant k$. Note that such clusters exist by condition 2 of Definition 1. Let $Q_i$ be the shortest path in $T$ between $C_{i-1}$ and $C_i$, $1 \leqslant i \leqslant k$. Let $Q_{k+1}$ be the shortest path in $T$ between $C_k$ and $B(v)$. Let $Q_{uv}(P) = \bigcup_{i=1}^{k+1} Q_i$ be a path between $B(u)$ and $B(v)$ and $Q'_{uv}$ be the shortest path between $B(u)$ and $B(v)$ in $T$. Note that $Q'_{uv} \subseteq Q_{uv}(P)$ for any path $P$ between $u$ and $v$. By condition 3 of Definition 1, $z_{i-1} \in Y$ for all $Y \in Q_i$, $1 \leqslant i \leqslant k+1$. Thus, any node of $Q_{uv}(P)$ and, hence, any node of $Q'_{uv}$ contains a vertex of any path $P$ between $u$ and $v$. By construction of $H$, $X \in Q'_{uv}$ and, therefore, $X$ is a separator between $u$ and $v$. $\square$

For any node $X$ of $H$, we construct a tree in $G$ in the following way. Let $U$ be a set of vertices of $G$ such that $U \subseteq \{V \setminus X\}$ and $B(u)$ is a descendant of $X$ in $H$ for $u \in U$. First, for each $u \in U$, we construct a $Q$-simple shortest path $P(u)$ from $u$ to $X$. Second, we construct a tree $t(X)$ spanning $X$ such that its diameter $diam_{t(X)} = \max_{x_1, x_2 \in X} \{dist_t(x_1, x_2)\}$ is minimal. Clearly, $diam_{t(X)} \leqslant 2R$. Finally, we build a graph $G_X = \bigcup_{u \in U} P(u) \cup t(X)$ and construct in a Breadth-First-Search manner starting from $t(X)$ a special spanning tree $\mathcal{T}$ of $G_X$.

**Lemma 6.** *A spanning tree $\mathcal{T}$ of $G_X$ can be constructed in such a way that for any $u \in U$, the path of $\mathcal{T}$ from $u$ to $X$ contains at most three vertices $z$ such that $B(z)$ is not a descendent of $X$ in $H$.*

**Proof.** Let $P(u)$ be a path in $G_X$ from $u \in U$ to $X$ and $W(P(u)) = \{z \in P(u) : B(z) \text{ is not a descendant of } X \text{ in } H\}$. Let $L_i = \{v \in V(G_X) : dist_{G_X}(v, X) = i\}$, $i \geqslant 0$, be the BFS-layers of $G_X$ with respect to $X$. A spanning tree $\mathcal{T}$ of $G_X$ can be constructed starting from $t(X)$ in the following way. For all $u \in L_1$, the $parent(u)$ is a vertex $x \in X$ such that $|W(P(u))|$ is minimum, where $P(u)$ is the path $\{u, x\}$ of $G_X$. For all $u \in L_i$, $i > 1$, $parent(u)$ is a neighbor $v \in L_{i-1}$ of $u$ in $G_X$ such that $|W(P(u))|$ is minimum, where $P(u) = \{u, P(v)\}$. The above construction guarantees that $u$ is connected to $X$ in $\mathcal{T}$ via a path $P(u)$ with minimum possible $|W(P(u))|$. Since there is a path in $G_X$ between $u \in U$ and $X$ that is $Q$-simple, by Corollary 2, $|W(P(u))| \leqslant 3$ for any $u \in U$. $\square$

**Lemma 7.** *Let $u$ and $v$ be two vertices of $G$, $X = nca_H(B(u), B(v))$, $\mathcal{T}$ be the tree associated with $X$, and $P_{\mathcal{T}}$ be a path from $u$ to $v$ in $\mathcal{T}$. Then there are no more than seven vertices $z$, such that $z \in P_{\mathcal{T}}$ and $B(z)$ is not a descendant of $X$ in $H$.*

**Proof.** By Lemma 6, there are at most 3 such vertices on the path between $u$ and $X$ and there are at most 3 more such vertices on the path between $v$ and $X$. Since $X$ has induced diameter 2, there is at most 1 other such vertex of $X$ that is on the path between $u$ and $v$ in $\mathcal{T}$. $\square$

**Lemma 8.** *Let $u$ and $v$ be two vertices of $G$, $X = nca_H(B(u), B(v))$, and $\mathcal{T}$ be the tree associated with $X$, then $dist_{\mathcal{T}}(u, v) \leqslant dist_G(u, v) + \Delta$, where $\Delta \leqslant diam_{t(X)}$.*

**Proof.** By Lemma 5, $X$ is a separator between $u$ and $v$. Let $P_G$ be a shortest path from $u$ to $v$ in $G$. Let $u' \in P_G$ be the vertex closest to $u$ such that $u' \in X$ and let $v' \in P_G$ be the vertex closest to $v$ such that $v' \in X$. Clearly,

$$dist_G(u, v) = dist_G(u, u') + dist_G(u', v') + dist_G(v', v). \tag{1}$$

Similarly, let $P_{\mathcal{T}}$ be the path from $u$ to $v$ in $\mathcal{T}$. Let $u'' \in P_{\mathcal{T}}$ be the vertex closest to $u$ such that $u'' \in X$ and let $v'' \in P_{\mathcal{T}}$ be the vertex closest to $v$ such that $v'' \in X$. Clearly,

$$dist_{\mathcal{T}}(u, v) = dist_{\mathcal{T}}(u, u'') + dist_{\mathcal{T}}(u'', v'') + dist_{\mathcal{T}}(v'', v). \tag{2}$$

From (1) and (2), we have

$$dist_{\mathcal{T}}(u, v) = dist_G(u, v) + [dist_{\mathcal{T}}(u, u'') - dist_G(u, u')]$$
$$+ [dist_{\mathcal{T}}(u'', v'') - dist_G(u', v')] + [dist_{\mathcal{T}}(v'', v) - dist_G(v', v)]. \tag{3}$$

We observe that, by construction of $\mathcal{T}$, $dist_{\mathcal{T}}(v'', u'') \leqslant diam_{t(X)}$, $dist_{\mathcal{T}}(u, u'') \leqslant dist_G(u, u')$, and $dist_{\mathcal{T}}(v'', v) \leqslant dist_G(v', v)$. Thus, from (3), we immediately have that $dist_{\mathcal{T}}(u, v) \leqslant dist_G(u, v) + \Delta$ where $\Delta \leqslant diam_{t(X)}$. $\square$

**Theorem 2.** *If a graph G admits an induced acyclic $(R, D)$-clustering with $R \leqslant 2$ and $D \leqslant 2$, then G has a loop-free routing scheme of deviation $\Delta \leqslant 2R$ with addresses and routing labels of size $O(\log^3 n / \log \log n)$ bits per vertex and $O(1)$ routing protocol.*

**Proof.** We associate a tree $\mathcal{T}(X)$, constructed as described above, with each node $X$ of the hierarchical tree $H$. Each vertex $u$ of $G$ only stores routing information for trees $\mathcal{T}(X)$ such that $B(u)$ is a descendant of $X$. Since the height of $H$ is at most $\log n$, there are at most $\log n$ such trees. For every pair of vertices $u$ and $v$ we can find $X = nca_H(B(u), B(v))$. This can be done in constant time by introducing a binary label of $O(\log n)$ bits in the address of each vertex [19]. By Lemma 8, we have $dist_{\mathcal{T}}(u, v) \leqslant dist_G(u, v) + \Delta$, where $\Delta \leqslant diam_{t(X)} \leqslant 2R$.

To implement the routing in the tree $\mathcal{T}(X)$ we use the scheme presented in [15]. This scheme uses addresses and labels of length $O(\log^2 n / \log \log n)$ bits and runs in constant time.

Along the route between $u$ and $v$ in $\mathcal{T}(X)$, there might be vertices $w$ such that $B(w)$ is not a descendant of $X$ in $H$ and therefore $w$ does not have the routing label for the tree $\mathcal{T}(X)$. By Lemma 7, the number of such vertices is constant. We store in advance port numbers for such vertices in routing labels, which requires each vertex $u$ to have an additional $O(\log n)$-bit label for each of $\log n$ trees. $\quad\square$

We distinguish a special case of induced acyclic clustering with radius $R = 1$.

**Corollary 3.** *If G admits an induced acyclic $(R, D)$-clustering with $R = 1$ and $D \leqslant 2$, then G has a loop-free routing scheme of deviation 2 with addresses and routing labels of size $O(\log^3 n / \log \log n)$ bits per vertex and $O(1)$ routing protocol.*

## 4. Chordal bipartite graphs

A bipartite graph is *chordal bipartite* if it does not contain any induced cycles of length greater than 4 [21].

Let $G = (X \cup Y, E)$ be a chordal bipartite graph. We construct a graph $G^+ = (X \cup Y, E^+)$ by adding edges between any two vertices $x_1, x_2 \in X$ for which there exists a vertex $y \in Y$ such that $x_1 y, x_2 y \in E$.

**Lemma 9.** *The graph $G^+$ is chordal.*

**Proof.** First notice that any $y \in Y$ is simplicial in $G^+$ by construction of $G^+$. Assume now, by contradiction, that there is an induced cycle $C_p$ of length $p$, $p > 3$, in $G^+$. Necessarily, all vertices of $C_p$ are from part $X$ of $G$, since $C_p$ is induced and all vertices from $Y$ are simplicial in $G^+$. Let $C_p = \{x_1, x_2, \ldots, x_p, x_1\}$. For any edge $x_i x_{i+1}$ of $C_p$ (including edge $x_p x_1$), since it is not an edge of $G$, there must be a vertex $y_i \in Y$ such that both $x_i$ and $x_{i+1}$ are adjacent to $y_i$ in $G$. Also, since $C_p$ is induced in $G^+$, $y_i$ is not adjacent to any other vertex of $C_p$. Therefore, a cycle $\{x_1, y_1, x_2, y_2, \ldots, x_p, y_p, x_1\}$ of $G$ must be induced. But, since its length is $2p \geqslant 8$, a contradiction with $G$ being a chordal bipartite graph arises. $\quad\square$

**Lemma 10.** *For any maximal clique $C$ of $G^+$ there exists a vertex $y \in Y$ such that $N_G[y] = C$.*

**Proof.** Let $|C| = p$. First note that, by construction of $G^+$, the clique $C$ can contain at most one vertex from $Y$. If $C$ contains a vertex from $Y$ (say $y \in C \cap Y$) then for all $v \in C \setminus \{y\}$, $vy$ is an edge of $G$, and therefore $C \subseteq N_G[y]$ must hold. Let now $C \cap Y = \emptyset$. By induction on $p$, we will show that there exists a vertex $y \in Y$ such that $C \subset N_G[y]$. Since $G$ is connected, any vertex $x \in C \subseteq X$ has a neighbor in $Y$. Also, by construction of $G^+$, for any edge $uv$ of $G^+$ with $u, v \in X$ there must exists a vertex $y \in Y$ adjacent to both $u$ and $v$. Assume now, by induction, that each $p - 1$ vertices of $C$ have a common neighbor $y \in Y$. Consider three different vertices $a$, $b$, and $c$ in $C$ and three corresponding vertices $a'$, $b'$, and $c'$ in $Y$ such that $C \setminus \{a\} \subset N_G[a']$, $C \setminus \{b\} \subset N_G[b']$, and $C \setminus \{c\} \subset N_G[c']$. Since the graph $G$ cannot have any induced cycles of length 6, the cycle $\{a, b', c, a', b, c', a\}$ of $G$ cannot be induced. Without loss of generality, assume that $a$ is adjacent to $a'$ in $G$. But then, all $p$ vertices of $C$ are contained in $N_G[a']$. $\quad\square$

From Lemmas 2, 9, and 10 we immediately establish the following result.

**Lemma 11.** *Any chordal bipartite graph $G$ admits an induced acyclic $(R, D)$-clustering with $R = 1$ and $D = 2$. Moreover, $\mathscr{C} = \{C_1, C_2, \ldots, C_{|Y|}\}$, where $C_i = N_G[y_i]$, $y_i \in Y$.*

Recalling Corollary 3, we conclude.

**Theorem 3.** *Any chordal bipartite graph $G$ admits a loop-free routing scheme of deviation $\Delta = 2$ with addresses and routing labels of size $O(\log^3 n / \log \log n)$ bits per vertex and $O(1)$ routing protocol.*

## 5. Homogeneously orderable graphs

A non-empty set $U \subseteq V$ is homogeneous in $G = (V, E)$ if all vertices of $U$ have the same neighborhood in $V \setminus U$. The *disk* of radius $k$ centered at $v$ is the set of vertices of distance at most $k$ from $v$: $D(v, k) = \{u \in V : dist_G(u, v) \leqslant k\} = \bigcup_{i=0}^{k} N^i(v)$. For $U \subseteq V$ we define $D(U, k) = \bigcup_{u \in U} D(u, k)$. The $k$th *power* $G^k$ of a graph $G = (V, E)$ is the graph with vertex set $V$ and edges between vertices $u$ and $v$ with distance $dist_G(u, v) \leqslant k$. A subset $U$ of $V$ is a *$k$-set* of $G$ if $U$ induces a clique in $G^k$.

A vertex $v$ of $G$ with $|V| > 1$ is *h-extremal* if there is a proper subset $H \subset D(v, 2)$ which is homogeneous in $G$ and for which $D(v, 2) \subseteq D(H, 1)$ holds. A vertex ordering $v_1, \ldots, v_n$ is a *homogeneous elimination ordering* of vertices of $G$ if for every $i$, $v_i$ is $h$-extremal in the induced subgraph $G_i = G(v_i \ldots v_n)$. $G$ is *homogeneously orderable* if it has a homogeneous elimination ordering. As it was shown in [3], homogeneously orderable graphs include such well known classes of graphs as distance-hereditary graphs, strongly chordal graphs, dually chordal graphs, and homogeneous graphs (for the definitions see [4]).

Let $U_1$, $U_2$ be disjoint sets in $V$. If every vertex of $U_1$ is adjacent to every vertex of $U_2$ then $U_1$ and $U_2$ form a *join*, denoted by $U_1 \bowtie U_2$. A set $U \subseteq V$ is *join-split* if $U$ is the join of two non-empty sets, i.e., $U = U_1 \bowtie U_2$.

The following theorem represents a well-known characterization of homogeneously orderable graphs.

**Theorem 4** (*Brandstädt et al. [3]*). *$G$ is homogeneously orderable if and only if $G^2$ is chordal and every maximal 2-set of $G$ is join-split.*

Taking into account Lemma 2 and considering $G^+ = G^2$, we immediately conclude.

**Corollary 4.** *Any homogeneously orderable graph $G$ admits an induced acyclic clustering with $R = 2$ and $D = 2$. The cluster set $\mathscr{C}$ is the collection of all maximal 2-sets of $G$.*

This corollary and Theorem 2 already imply for homogeneously orderable graphs existence of a loop-free routing scheme of deviation $\Delta = 4$ with addresses and routing labels of size $O(\log^3 n / \log \log n)$ bits per vertex and $O(1)$ routing protocol. In what follows, we will show that, in fact, the scheme described in Section 3 gives for homogeneously orderable graphs a routing scheme of deviation $\Delta = 2$.

For a vertex function $r : V \to \mathscr{N}$ (note that zero is assumed to be a natural number), a clique $C \subseteq V$ *r-dominates* a subset $S \subseteq V$ if for each vertex $u \in S \setminus C$ there is a vertex $x \in C$ such that $dist_G(u, x) \leqslant r(u)$ holds. We will use the following known result.

**Theorem 5** (*Dragan and Nicolai [13]*). *For any homogeneously orderable graph $G$ with vertex function $r : V \to \mathscr{N}$ and for any subset $S$ of $V$, $S$ is r-dominated by some clique $C$ if and only if $dist_G(x, y) \leqslant r(x) + r(y) + 1$ for all $x, y \in S$.*

**Lemma 12.** *Let $U = U_1 \bowtie U_2$ be a maximal 2-set of a homogeneously orderable graph $G$, $z$ be a vertex of $G$ such that $z \notin U$, and $d = dist_G(z, U)$ be the distance between $z$ and the set $U$. Then, for any two vertices $v, w \in U$ such that $dist_G(z, v) = dist_G(z, w) = d$, either $v, w \in U_1$ or $v, w \in U_2$ holds.*

**Proof.** Assume, by way of contradiction, that $v \in U_1$ and $w \in U_2$. Since $U$ is join-split, $dist_G(v, w) = 1$. Let $S = \{z, v, w\}$ and a vertex function $r$ be defined as $r(z) = d - 1$, $r(v) = r(w) = 0$ and $r(u) = diam(G) := diam_G(V)$ for any $u \in V \setminus S$. Note that the inequality $dist_G(x, y) \leqslant r(x) + r(y) + 1$ holds for all $x, y \in S$. According to Lemma 5, $S$ is $r$-dominated by a clique $C \subseteq V$. Thus, there must be a vertex $z' \in C$ such that

$dist_G(z', v) = dist_G(z', w) = 1$ and $dist_G(z, z') = d - 1$. It is easy to see that $dist_G(z', u) \leqslant 2$ for any $u \in U$ and, since $U$ is a maximal 2-set, $z' \in U$ must hold. Since $dist_G(z, z') = d - 1$, we obtain $dist_G(z, U) = d - 1$, which is a contradiction. □

Let $T$ be a tree decomposition of a homogeneously orderable graph $G = (V, E)$ and $H$ be its hierarchical tree. With each node $X = U_1 \bowtie U_2$ of $H$ we associate a spanning tree $\mathcal{T}$ of $G_X$ as described in Section 3, where a spanning tree $t(X)$ of $X$ is constructed as follows. Beginning at an arbitrary vertex $s_1 \in U_1$, we visit all vertices in $U_2$, then continuing from any vertex $s_2 \in U_2$, we visit all vertices in $U_1 \setminus \{s_1\}$. Clearly, $diam_{t(X)} = 3$.

**Lemma 13.** *Let $u$ and $v$ be two vertices of a homogeneously orderable graph $G$, $X = nca_H(B(u), B(v))$, and $\mathcal{T}$ be a tree associated with node $X$. Then $dist_{\mathcal{T}}(u, v) \leqslant dist_G(u, v) + \Delta$ with $\Delta = 2$.*

**Proof.** From Lemma 8, we have

$$dist_{\mathcal{T}}(u, v) = dist_G(u, v) + [dist_{\mathcal{T}}(u, u'') - dist_G(u, u')]$$

$$+ [dist_{\mathcal{T}}(u'', v'') - dist_G(u', v')] + [dist_{\mathcal{T}}(v'', v) - dist_G(v', v)], \qquad (4)$$

where $u'$ and $u''$ are vertices closest to $u$ such that $u' \in P_G$, $u'' \in P_{\mathcal{T}}$, $u', u'' \in X$, $v'$ and $v''$ are vertices closest to $v$ such that $v' \in P_G$, $v'' \in P_{\mathcal{T}}$, $v', v'' \in X$, and $P_G$ and $P_{\mathcal{T}}$ are shortest paths from $u$ to $v$ in $G$ and in $\mathcal{T}$, respectively.

We notice that, by construction of $\mathcal{T}$, $dist_{\mathcal{T}}(v'', u'') \leqslant 3$, $dist_{\mathcal{T}}(u, u'') \leqslant dist_G(u, u')$, and $dist_{\mathcal{T}}(v'', v) \leqslant dist_G(v', v)$. Hence, $dist_{\mathcal{T}}(u, v) \leqslant dist_G(u, v) + 2$, if at least one of the following holds: $dist_{\mathcal{T}}(u, u'') < dist_G(u, u')$, $dist_{\mathcal{T}}(v'', v) < dist_G(v', v)$, or $dist_{\mathcal{T}}(u'', v'') < 3$.

Therefore, assume that $dist_{\mathcal{T}}(u, u'') = dist_G(u, u')$, $dist_{\mathcal{T}}(v'', v) = dist_G(v', v)$, and $dist_{\mathcal{T}}(u'', v'') = 3$. Since $dist_{\mathcal{T}}(u'', v'') = 3$, $u''$ and $v''$ belong to different parts of $U = U_1 \bowtie U_2$. Without loss of generality, assume that $u'' \in U_1$ and $v'' \in U_2$. Since $dist_{\mathcal{T}}(u, u'') = dist_G(u, u'') = dist_G(u, u')$ and $dist_{\mathcal{T}}(v'', v) = dist_G(v'', v) = dist_G(v', v)$, by Lemma 12, we have $u' \in U_1$ and $v' \in U_2$. Thus, $u' \neq v'$, i.e., $dist_G(u', v') > 0$, and from (4) we immediately have $dist_{\mathcal{T}}(u, v) \leqslant dist_G(u, v) + \Delta$, where $\Delta = 2$. □

Taking into account Theorem 2, we obtain the following.

**Theorem 6.** *Any homogeneously orderable graph $G$ admits a loop-free routing scheme of deviation $\Delta = 2$ with addresses and routing labels of size $O(\log^3 n / \log \log n)$ bits per vertex and $O(1)$ routing protocol.*

## 6. Interval graphs

The intersection graph of a family of $n$ sets is the graph where the vertices are the sets, and the edges are the pairs of sets that intersect. A graph $G$ is an *interval graph* if it is the intersection graph of a finite set of intervals (line segments) on a line.

Let $G = (V, E)$ be an interval graph. Since for a given interval graph the interval model of $G$ (i.e., a corresponding set of intervals) can be constructed in linear $O(|V| + |E|)$ time (see, e.g., [2,6,24]), in what follows, we will assume that an interval model of $G$ is given.

It is well known [21] that interval graphs form a proper subclass of chordal graphs. Hence, by Theorem 1, we have:

**Lemma 14.** *Any interval graph $G$ admits an induced acyclic $(R, D)$-clustering with $R = D = 1$, where clusters are the maximal cliques of $G$.*

This lemma and Theorem 2 already imply for interval graphs existence of a loop-free routing scheme of deviation $\Delta = 2$ with addresses and routing labels of size $O(\log^3 n / \log \log n)$ bits per vertex and $O(1)$ routing protocol. In what follows, we will show that even a deviation $\Delta = 1$ can be achieved.

**Lemma 15.** *For any maximal clique $X$ of an interval graph $G = (V, E)$ there exist two vertices $x_l$ and $x_r$ such that $dist_G(v, X) = dist_G(v, x_l)$ or $dist_G(v, X) = dist_G(v, x_r)$ for any vertex $v \in V \setminus X$.*
Fig. 5. An interval graph and its interval model. For $X = \{d, f, h, i\}$, $x_r = h$ and $x_l = d$.

**Proof.** We consider an interval model of $G$ and consequently assign numbers from 1 to $2n$ to the endpoints of the line segments, from left to right. Each vertex $v$ of the graph is represented by a distinct pair of integers $l(v)$, $r(v)$, where $l(v)$ and $r(v)$ are the numbers of the left and right endpoints of the segment representing vertex $v$. For any maximal clique $X$, let $x_l$ be a vertex of $X$ such that $l(x_l)$ is smallest and $x_r$ be a vertex of $X$ such that $r(x_r)$ is largest. See Fig. 5 for an illustration.

Let $x$ be a vertex of $X$ such that $P = \{v, z_1, \ldots, z_k, x\}$ is a shortest path from $v$ to $X$. By definition of $x_l$ and $x_r$, $z_k$ must be adjacent to $x_l$ or to $x_r$. Thus, either $P' = \{v, z_1, \ldots, z_k, x_l\}$ or $P'' = \{v, z_1, \ldots, z_k, x_r\}$ is a shortest path from $v$ to $X$. $\square$

Let $H$ be a hierarchical tree for $G$. For any node $X$ of $H$, we construct a spanning tree $\mathcal{T}$ of $G_X$ in the following way. Let $U$ be a set of vertices of $G$ such that $U \subseteq \{V \backslash X\}$ and $B(u)$ is a descendant of $X$ in $H$ for any $u \in U$. For each $u \in U$, we construct a $Q$-simple shortest path $P(u) = \{u, z_1, \ldots, z_k, x\}$ from $u$ to $X$ such that $x$ is either $x_l$ or $x_r$. Since $X$ is a clique, a spanning tree $t(X)$ is a star with center at $x_l$. Finally, we build a graph $G_X = \bigcup_{u \in U} P(u) \cup t(X)$ and construct in a Breadth-First-Search manner starting from $t(X)$ a special spanning tree $\mathcal{T}$ of $G_X$ (see Lemma 6).

**Lemma 16.** *Let $u$ and $v$ be two vertices of an interval graph $G$, $X = nca_H(B(u), B(v))$, and $\mathcal{T}$ be a tree associated with $X$. Then, $dist_{\mathcal{T}}(u, v) \leqslant dist_G(u, v) + \Delta$ with $\Delta = 1$.*

**Proof.** From Lemma 8, have

$$dist_{\mathcal{T}}(u, v) = dist_G(u, v) + [dist_{\mathcal{T}}(u, u'') - dist_G(u, u')]$$
$$+ [dist_{\mathcal{T}}(u'', v'') - dist_G(u', v')] + [dist_{\mathcal{T}}(v'', v) - dist_G(v', v)], \tag{5}$$

where $u'$ and $u''$ are vertices closest to $u$ such that $u' \in P_G$, $u'' \in P_{\mathcal{T}}$, $u', u'' \in X$, $v'$ and $v''$ are vertices closest to $v$ such that $v' \in P_G$, $v'' \in P_{\mathcal{T}}$, $v', v'' \in X$, and $P_G$ and $P_{\mathcal{T}}$ are shortest paths from $u$ to $v$ in $G$ and in $\mathcal{T}$, respectively.

We notice that, by construction of $\mathcal{T}$, $u''$ and $v''$ are $x_l$ or $x_r$. Taking into account that $dist_{\mathcal{T}}(v'', u'') \leqslant 1$, $dist_{\mathcal{T}}(u, u'') = dist_G(u, u')$ and $dist_{\mathcal{T}}(v'', v) = dist_G(v', v)$, from (5), we immediately obtain $dist_{\mathcal{T}}(u, v) \leqslant dist_G(u, v) + 1$. $\square$

Thus, from Theorem 2, we have the following.

**Theorem 7.** *Any interval graph $G$ admits a loop-free routing scheme of deviation $\Delta = 1$ with addresses and routing labels of size $O(\log^3 n / \log \log n)$ bits per vertex and $O(1)$ routing protocol.*
