DESIGN & ANALYSIS OF ALGORITHM

Game of Life 2

Get the initial configuration of living cells and use it to calculate an array holding the neighbor counts of all cells. Determine the cells that will become alive and that will become dead in the first generation;

Repeat the following steps as long as desired:

Vivify each cell that is ready to become alive;

Kill each cell that is ready to die;

Write out the map for the user;

Increase the neighbor counts for each neighbor of each cell that has become alive; If a neighbor count reaches the appropriate value, then keep track of the cell as a candidate to be made alive or dead in the next generation;

Decrease the neighbor counts for each neighbor of each cell that has become dead; If a neighbor count reaches the appropriate value, then keep track of the cell as a candidate to be made alive or dead in the next generation.

DESIGN &
ALYSIS OF
ALGORITHM

LECT-02, S-8
ALG00S, javed@kent.edu
Javed I. Khan @1999

```
void AddNeighbors(ListEntry cell);
```

Pre: cell has just become alive.

Post: Array numbernbrs has increased counts for all the cells neighboring cell. If the cell thereby becomes a candidate to be vivified [*resp.* killed] then the cell has been added to list maylive [*resp.* maydie].

Uses: Function AddList; changes array numbernbrs and lists maylive and maydie as global variables (side effects).

DESIGN &
ALYSIS OF
ALGORITHM

```
void Vivify(ListEntry cell);
```

Pre: The cell is a candidate to become alive.

Post: Checks that cell meets all the requirements to become alive. If not, no change is made. If so, then cell is added to the list newlive, and array map is updated.

Uses: Function AddList, array numbernbrs, changes array map and list newlive as global variables (side effects).

At the beginning of the main loop, list maylive contains only dead cells, and list maydie contains only living cells. These lists may contain duplicate entries or spurious entries with wrong neighbor counts. The lists newlive and newdie are empty.

ANALYSIS OF
ALGORITHM

LECT-02, S-12
ALG00S, javed@kent.edu
Javed I. Khan@1999

Analysis of Version 2

Analysis of Version 2

- Ignore I/O
- All most all work is done in the 4 traversing statements.
- The amount of work is no longer dependant on the size of the grid but on the number of state changes.
- If there are 50 cells occupied for a typical configuration, then on the average there will be 25 state changes.

Comparisons

- Time complexity
 - Total= $25*(4+54+4+54) \approx 2900$ as opposed to 18,000 statements!
 - 6 Times saving!
- How about Space Complexity?
- V.1 requires about $2x20x60$ bits= 300 bytes.
- V.2 needs
 - 150 bytes for one map.
 - 2400 bytes numbers for 1200 grid points.
 - $4x600=2400$ bytes for four lists (assuming 25% per list)
 - A total of 5000 bytes!
- Plus the extra programming effort!
