

MEDIUM ACCESS PROTOCOLS

28

Static Channel Allocation

- Traditional Approach of sharing channel is to allot a separate
 - Time slot (TDM) or
 - Frequency (FDM)
- But such approach is not suitable for computer communication, because:
 - Large number of sender means large delay.
 - Time/Frequency wastage if everybody is not transmitting.
 - Difficult to manage dynamic addition and deletion of stations.

COMPUTER
COMMUNICATION
NETWORK

Dynamic Channel Allocation: Few Definitions

- Station Model
 - N independent stations. The probability of a frame generation in an time interval of length is $\lambda \cdot \Delta t$. λ is the uniform frame arrival rate.
- Single Channel Assumption
 - All station transmits to only one medium.

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-30
NET98F, javed@kent.edu
Javed I. Khan@1998

Few More Concepts

- Collision Assumption
 - all station can detect collisions. It requires retransmission.
- Continuous Time/Slotted Time
 - stations are allowed to transmit any time/ or at specific interval.
- Carrier Sense/No Carrier Sense
 - Stations can tell if anyone else is transmitting or not.

NET98F, javed@kent.edu
Javed I. Khan@1998

ALOHA Protocol

- In 1970, Normal Abramson and his colleagues at the University of Hawaii devised this method. The idea has since been extended and has found its way in almost all shared media protocols.
- The Basic Concept:
 - User is allowed to transmit whenever they have data to send.
 - There will be occasional collisions.
 - Due to feedback property of medium the transmitter will know.
 - It will retransmit just waiting after random amount of time.

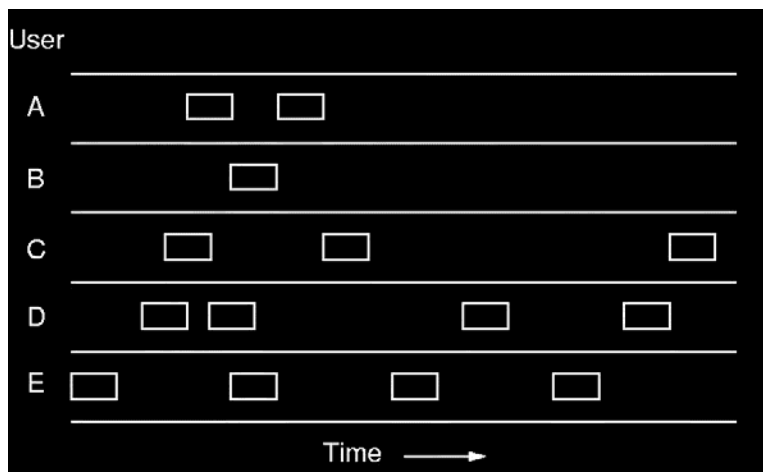

- It is Extremely simple, as no inter station co-ordination is required. All stations can act independently.

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-32
NET98F, javed@kent.edu
Javed I. Khan@1998

ALOHA Protocol

- Stations can transmit independently. Only occasionally there will be collision under light load.

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-33
NET98F, javed@kent.edu
Javed I. Khan@1998

Performance of ALOHA

- S = Frames generated per frame time.
 - If $S > 1$ then user community is generating too much frames.
 - For reasonable throughput $0 < S < 1$
- G = Average frames transmitted per frame time.
 - $G > S$
 - at low load $G \approx S$
 - at high load there will be many collisions $G \gg S$
- Relationship between S and G
 - Under all loads, the throughput S is just the transmitted load G times the probability that there was no collision P_0 .
 - $S = G \cdot P_0$

COMMUNICATION
NETWORK

LECT-5, S-34
NET98F, javed@kent.edu
Javed I. Khan@1998

Performance of ALOHA

- With **rate of arrival** λ , the probability that k frames are generated during a given frame time is given by the Poisson's distribution:

$$pr[k] = \frac{\lambda^k e^{-\lambda}}{k!}$$

- What is the probability that 0 frames were generated during a given frame time?

$$p_0 = pr[0] = \frac{\lambda^0 e^{-\lambda}}{0!} = e^{-\lambda}$$

- What is the arrival rate and frame time slot for ALOHA?

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-35
NET98F, javed@kent.edu
Javed I. Khan@1998

Vulnerable Period of ALOHA

- The vulnerable period is two frame time long.

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-36
NET98F, javed@kent.edu
Javed I. Khan@1998

Efficiency of ALOHA

- The mean number of frames generated in an interval of two frame time long is $2G$.
 - Probability of collision avoidance is:

$$p_0 = e^{-\lambda} = e^{-2G}$$

- The throughput is

$$S = GP_0 = Ge^{-2G}$$

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-37
NET98F, javed@kent.edu
Javed I. Khan@1998

Throughput vs. Traffic for ALOHA

- The peak is at $G=0.5$, with $s=1/2e = 0.184$
- That is the cost of independence!

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-38
NET98F, javed@kent.edu
Javed I. Khan@1998

Slotted ALOHA

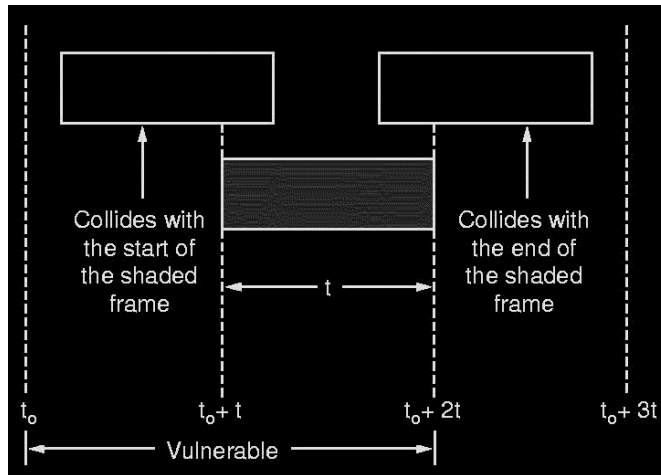

- In 1972, Robert's published a method for doubling the capacity of ALOHA system.
- Idea:
 - Divide the time in slots, each interval corresponds to one frame. (let one station emit a pip at the start of each interval).
 - A computer can transmit only at the beginning of a slot.

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-39
NET98F, javed@kent.edu
Javed I. Khan@1998

Vulnerable Period of Slotted ALOHA

- The vulnerable period is now one slot.

Efficiency of ALOHA

- The mean number of frames generated in an interval of two frame time long is G .
 - Probability of collision avoidance is:

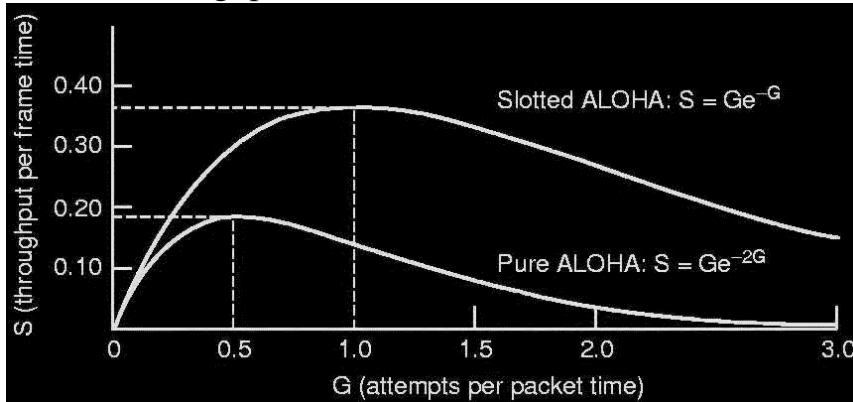

$$P_0 = e^{-\lambda} = e^{-G}$$

- The throughput is

$$S = GP_0 = Ge^{-G}$$

Throughput vs. Traffic for Slotted ALOHA

- The peak is at $G=1$, with $s=1/e = 0.368$ compared to .184 of pure ALOHA

How many times a station have to try?

- The probability that a slotted ALOHA will avoid collision is

$$p_0 = e^{-\lambda} = e^{-G}$$

- The probability that exactly k-transmission will be required:

$$p_k = e^{-G} (1 - e^{-G})^{k-1}$$

- The expected number of transmission is

$$E = \sum_{k=1}^{\infty} k \cdot p_k = e^G$$

Improvements: CSMA Carrier Sense Multiple Access Protocols

- In ALOHA, stations do not pay attention to what other stations are doing. In local area networks perhaps they can. Here are some ideas:
- 1-persistent CSMA.
 - Before transmission sense the carrier.
 - If no one else is transmitting only then transmit.
 - If others are transmitting, wait till the end
 - try transmission at the end of current transmission.

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-44
NET98F, javed@kent.edu
Javed I. Khan@1998

Non-persistent CSMA

- Idea:
 - try to be less greedy.
 - Before transmission sense the carrier.
 - If no one else is transmitting only then transmit.
 - If others are transmitting, wait do not keep on sensing the channel.
 - Wait a random amount of time and and repeat the process.

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-45
NET98F, javed@kent.edu
Javed I. Khan@1998

p-persistent CSMA

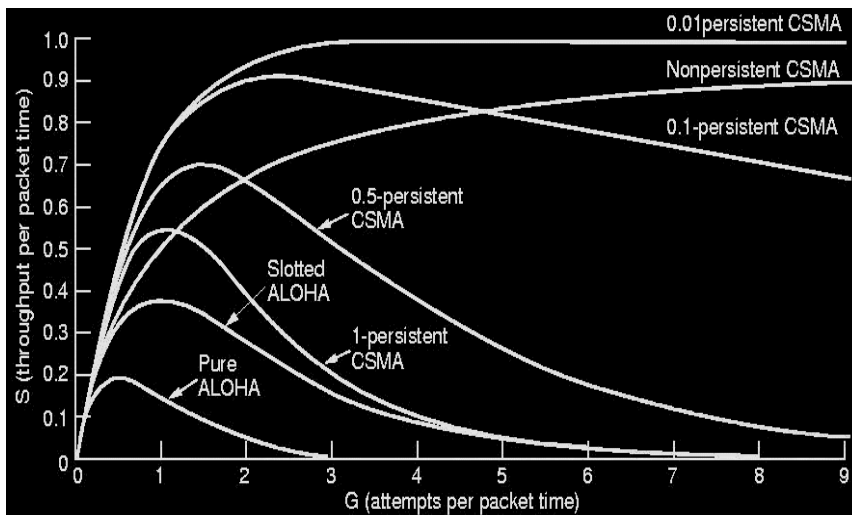

- Idea:
 - Try to be moderately greedy.
 - Before transmission sense the carrier.
 - If no one else is transmitting only then transmit.
 - If others are transmitting, flip a coin with probability p of head.
 - If head retransmit at the end of current transmission.
 - If tail, wait and flip the coin again at the end of the second transmission. If tail again.. Repeat..

Example Real Protocol Ethernet (IEEE 802.3)

- Cabling:

Name	Cable	Max. segment	Nodes/seg.	Advantages
10Base5	Thick coax	500 m	100	Good for backbones
10Base2	Thin coax	200 m	30	Cheapest system
10Base-T	Twisted pair	100 m	1024	Easy maintenance
10Base-F	Fiber optics	2000 m	1024	Best between buildings

Collision Detection

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-60
NET98F, javed@kent.edu
Javed I. Khan@1998

Binary Exponential Back-off

- Idea:
 - after each collision, each station waits either 0 or 1 timeslot before trying again.
 - If there is again collision, the stations pick 0, 1, 2 or 3, and wait that many time slots before retransmitting.

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-61
NET98F, javed@kent.edu
Javed I. Khan@1998

Channel Efficiency

- Probability of transmission for one station = p
- Probability of transmission in one slot = A
- Duration of a slot = 2λ
- Mean frame duration = P
- Frame length = F
- Network bandwidth = B
- Cable length = L

COMPUTER
COMMUNICATION
NETWORK

LECT-5, S-62
NET98F, javed@kent.edu
Javed I. Khan@1998

How many times a station have to try?

- Let p is the probability that one station acquires the channel. The probability that any one of the k stations acquires the channel in a slot is: $A = k \cdot p \cdot (1 - p)^{k-1}$

- A is maximized when: $p_0 = 1/k$, $A \rightarrow 1/e$, $k \rightarrow \infty$
- The probability that it requires exactly j slots is:

$$A(1 - A)^{j-1}$$

- The average number of slots per contention is:

$$\sum_{j=0}^{\infty} j \cdot A \cdot (1 - A)^{j-1} = 1 / A$$

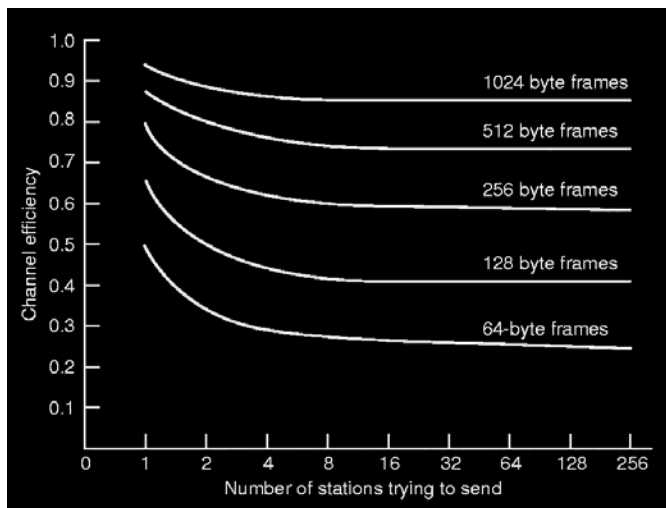

- Channel Efficiency = $\eta = \frac{P}{P + \frac{2\lambda}{A}} = \frac{1}{1 + 2BLE/cF}$
