

# Lecture 7: Minimum Spanning Trees and Prim's Algorithm

CLRS Chapter 23

## Outline of this Lecture

- Spanning trees and minimum spanning trees.
- The minimum spanning tree (MST) problem.
- The generic algorithm for MST problem.
- Prim's algorithm for the MST problem.
  - The algorithm
  - Correctness
  - Implementation + Running Time

## Spanning Trees

**Spanning Trees:** A **subgraph**  $T$  of a undirected graph  $G = (V, E)$  is a **spanning tree** of  $G$  if it is a tree and contains every vertex of  $G$ .

**Example:**

Graph

spanning tree 1

spanning tree 2

spanning tree 3

## Spanning Trees

**Theorem:** Every connected graph has a spanning tree.

**Question:** Why is this true?

**Question:** Given a connected graph  $G$ , how can you find a spanning tree of  $G$ ?

## Weighted Graphs

**Weighted Graphs:** A weighted graph is a graph, in which each edge has a weight (some real number).

**Weight of a Graph:** The sum of the weights of all edges.

**Example:**

weighted graph

Tree 1.  $w=74$

Tree 2,  $w=71$

Tree 3,  $w=72$

Minimum spanning tree

## Minimum Spanning Trees

A **Minimum Spanning Tree** in an undirected connected weighted graph is a spanning tree of **minimum weight** (among all spanning trees).

**Example:**

weighted graph

Tree 1.  $w=74$

Tree 2,  $w=71$

Tree 3,  $w=72$

Minimum spanning tree

## Minimum Spanning Trees

**Remark:** The minimum spanning tree may not be unique. However, if the weights of all the edges are pairwise distinct, it is indeed unique (we won't prove this now).

**Example:**

## Minimum Spanning Tree Problem

**MST Problem:** Given a connected weighted undirected graph  $G$ , design an algorithm that outputs a minimum spanning tree (MST) of  $G$ .

**Question:** What is most intuitive way to solve?

**Generic approach:** A tree is an acyclic graph. The idea is to start with an empty graph and try to add edges one at a time, always making sure that what is built remains acyclic. And if we are sure every time the resulting graph always is a subset of some minimum spanning tree, we are done.

## Generic Algorithm for MST problem

Let  $A$  be a set of edges such that  $A \subseteq T$ , where  $T$  is a MST. An edge  $(u, v)$  is a *safe edge* for  $A$ , if  $A \cup \{(u, v)\}$  is also a subset of some MST.

If at each step, we can find a safe edge  $(u, v)$ , we can 'grow' a MST. This leads to the following generic approach:

```
Generic-MST( $G, w$ )
```

```
  Let  $A = \text{EMPTY};$ 
```

```
  while  $A$  does not form a spanning tree
```

```
    find an edge  $(u, v)$  that is safe for  $A$ 
```

```
    add  $(u, v)$  to  $A$ 
```

```
  return  $A$ 
```

How can we find a safe edge?

## How to find a safe edge

We first give some definitions. Let  $G = (V, E)$  be a connected and undirected graph. We define:

**Cut** A **cut**  $(S, V - S)$  of  $G$  is a partition of  $V$ .

**Cross** An edge  $(u, v) \in E$  **crosses** the cut  $(S, V - S)$  if one of its endpoints is in  $S$ , and the other is in  $V - S$ .

**Respect** A cut **respects** a set  $A$  of edges if no edge in  $A$  crosses the cut.

**Light edge** An edge is a **light edge** crossing a cut if its weight is the minimum of any edge crossing the cut.

## How to find a safe edge

### Lemma

Let  $G = (V, E)$  be a connected, undirected graph with a real-valued weight function  $w$  defined on  $E$ . Let  $A$  be a subset of  $E$  that is included in some minimum spanning tree for  $G$ , let  $(S, V - S)$  be *any* cut of  $G$  that respects  $A$ , and let  $(u, v)$  be a light edge crossing the cut  $(S, V - S)$ . Then, edge  $(u, v)$  is safe for  $A$ .

It means that we can find a safe edge by

1. first finding a cut that respects  $A$ ,
2. then finding the light edge crossing that cut.

That light edge is a safe edge.

## Proof

1. Let  $A \subseteq T$ , where  $T$  is a MST. Suppose  $(u, v) \notin T$ .
2. The trick is to construct *another* MST  $T'$  that contains both  $A$  and  $(u, v)$ , thereby showing  $(u, v)$  is a safe edge for  $A$ .

3. Since  $u$ , and  $v$  are on opposite sides of the cut  $(S, V - S)$ , there is at least one edge in  $T$  on the path from  $u$  to  $v$  that *crosses* the cut. Let  $(x, y)$  be such edge. Since the cut respects  $A$ ,  $(x, y) \notin A$ .

Since  $(u, v)$  is a light edge crossing the cut, we have  $w(x, y) \geq w(u, v)$ .

4. Add  $(u, v)$  to  $T$ , it creates a cycle. By removing an edge from the cycle, it becomes a tree again. In particular, we remove  $(x, y)$  ( $\notin A$ ) to make a new tree  $T'$ .

5. The weight of  $T'$  is

$$\begin{aligned}w(T') &= w(T) - w(x, y) + w(u, v) \\ &\leq w(T)\end{aligned}$$

6. Since  $T$  is a MST, we must have  $w(T) = w(T')$ , hence  $T'$  is also a MST.

7. Since  $A \cup \{(u, v)\}$  is also a subset of  $T'$  (a MST),  $(u, v)$  is safe for  $A$ .

## Prim's Algorithm

The generic algorithm gives us an idea how to 'grow' a MST.

If you read the theorem and the proof carefully, you will notice that the choice of a cut (and hence the corresponding light edge) in each iteration is immaterial. We can select *any cut* (that respects the selected edges) and find the light edge crossing that cut to proceed.

The *Prim's* algorithm makes a nature choice of the cut in each iteration – it grows a single tree and adds a light edge in each iteration.

## Prim's Algorithm : How to grow a tree

### Grow a Tree

- Start by picking any vertex  $r$  to be the root of the tree.
- While the tree does not contain all vertices in the graph  
find shortest edge leaving the tree  
and add it to the tree .

Running time is  $O((|V| + |E|) \log |V|)$ .

## More Details

**Step 0:** Choose any element  $r$ ; set  $S = \{r\}$  and  $A = \emptyset$ . (Take  $r$  as the root of our spanning tree.)

**Step 1:** Find a lightest edge such that one endpoint is in  $S$  and the other is in  $V \setminus S$ . Add this edge to  $A$  and its (other) endpoint to  $S$ .

**Step 2:** If  $V \setminus S = \emptyset$ , then stop & output (minimum) spanning tree  $(S, A)$ . Otherwise go to Step 1.

The idea: expand the current tree by adding the lightest (shortest) edge leaving it and its endpoint.

# Prim's Algorithm

## Worked Example

Connected graph

Step 0

$S = \{a\}$

$V \setminus S = \{b, c, d, e, f, g\}$

lightest edge = {a,b}

## Prim's Algorithm

### Prim's Example – Continued

Step 1.1 before

$S = \{a\}$

$V \setminus S = \{b, c, d, e, f, g\}$

$A = \{\}$

lightest edge =  $\{a, b\}$

Step 1.1 after

$S = \{a, b\}$

$V \setminus S = \{c, d, e, f, g\}$

$A = \{\{a, b\}\}$

lightest edge =  $\{b, d\}, \{a, c\}$

## Prim's Algorithm

### Prim's Example – Continued

Step 1.2 before

$S = \{a, b\}$

$V \setminus S = \{c, d, e, f, g\}$

$A = \{\{a, b\}\}$

lightest edge =  $\{b, d\}, \{a, c\}$

Step 1.2 after

$S = \{a, b, d\}$

$V \setminus S = \{c, e, f, g\}$

$A = \{\{a, b\}, \{b, d\}\}$

lightest edge =  $\{d, c\}$

## Prim's Algorithm

### Prim's Example – Continued

Step 1.3 before  
 $S = \{a, b, d\}$   
 $V \setminus S = \{c, e, f, g\}$   
 $A = \{(a, b), (b, d)\}$   
lightest edge =  $\{d, c\}$

Step 1.3 after  
 $S = \{a, b, c, d\}$   
 $V \setminus S = \{e, f, g\}$   
 $A = \{(a, b), (b, d), (c, d)\}$   
lightest edge =  $\{c, f\}$

## Prim's Algorithm

### Prim's Example – Continued

Step 1.4 before

$S = \{a, b, c, d\}$

$V \setminus S = \{e, f, g\}$

$A = \{\{a, b\}, \{b, c\}, \{c, d\}\}$

lightest edge =  $\{c, f\}$

Step 1.4 after

$S = \{a, b, c, d, f\}$

$V \setminus S = \{e, g\}$

$A = \{\{a, b\}, \{b, c\}, \{c, d\}, \{c, f\}\}$

lightest edge =  $\{f, g\}$

## Prim's Algorithm

### Prim's Example – Continued

Step 1.5 before

$S = \{a, b, c, d, f\}$

$V \setminus S = \{e, g\}$

$A = \{\{a, b\}, \{b, d\}, \{c, d\}, \{c, f\}\}$

lightest edge =  $\{f, g\}$

Step 1.5 after

$S = \{a, b, c, d, f, g\}$

$V \setminus S = \{e\}$

$A = \{\{a, b\}, \{b, d\}, \{c, d\}, \{c, f\}, \{f, g\}\}$

lightest edge =  $\{f, e\}$

## Prim's Algorithm

### Prim's Example – Continued

Step 1.6 before

$S = \{a, b, c, d, f, g\}$

$V \setminus S = \{e\}$

$A = \{\{a, b\}, \{b, d\}, \{c, d\}, \{c, f\}, \{f, g\}\}$

lightest edge =  $\{f, e\}$

Step 1.6 after

$S = \{a, b, c, d, e, f, g\}$

$V \setminus S = \{\}$

$A = \{\{a, b\}, \{b, d\}, \{c, d\}, \{c, f\}, \{f, g\}, \{f, e\}\}$

MST completed

## Recall Idea of Prim's Algorithm

**Step 0:** Choose any element  $r$  and set  $S = \{r\}$  and  $A = \emptyset$ .  
(Take  $r$  as the root of our spanning tree.)

**Step 1:** Find a lightest edge such that one endpoint is in  $S$  and the other is in  $V \setminus S$ . Add this edge to  $A$  and its (other) endpoint to  $S$ .

**Step 2:** If  $V \setminus S = \emptyset$ , then stop and output the minimum spanning tree  $(S, A)$ .  
Otherwise go to Step 1.

### Questions:

- Why does this produce a **Minimum** Spanning Tree?
- How does the algorithm find the lightest edge and update  $A$  efficiently?
- How does the algorithm update  $S$  efficiently?

## Prim's Algorithm

**Question:** How does the algorithm update  $S$  efficiently?

**Answer:** Color the vertices. Initially all are white. Change the color to black when the vertex is moved to  $S$ . Use  $\text{color}[v]$  to store color.

**Question:** How does the algorithm find the lightest edge and update  $A$  efficiently?

**Answer:**

- (a) Use a  $\text{priority queue}$  to find the lightest edge.
- (b) Use  $\text{pred}[v]$  to update  $A$ .

## Reviewing Priority Queues

**Priority Queue** is a data structure (can be implemented as a heap) which supports the following operations:

**insert( $u, key$ ):**

Insert  $u$  with the key value  $key$  in  $Q$ .

**$u = \text{extractMin}()$ :**

Extract the item with the minimum key value in  $Q$ .

**decreaseKey( $u, new\text{-}key$ ):**

Decrease  $u$ 's key value to  $new\text{-}key$ .

**Remark:** Priority Queues can be implemented so that each operation takes time  $O(\log |Q|)$ . See CLRS!

## Using a Priority Queue to Find the Lightest Edge

Each item of the queue is a triple  $(u, \text{pred}[u], \text{key}[u])$ , where

- $u$  is a vertex in  $V \setminus S$ ,
- $\text{key}[u]$  is the weight of the lightest edge from  $u$  to any vertex in  $S$ , and
- $\text{pred}[u]$  is the endpoint of this edge in  $S$ .

The array is used to build the MST tree.

$\text{key}[f] = 8, \text{pred}[f] = e$   
 $\text{key}[i] = \text{infinity}, \text{pred}[i] = \text{nil}$   
 $\text{key}[g] = 16, \text{pred}[g] = c$   
 $\text{key}[h] = 24, \text{pred}[h] = b$   
 $\rightarrow f$  has the minimum key

new edge

$\text{key}[i] = 23, \text{pred}[i] = f$

After adding the new edge and vertex  $f$ , update the  $\text{key}[v]$  and  $\text{pred}[v]$  for each vertex  $v$  adjacent to  $f$

## Description of Prim's Algorithm

**Remark:**  $G$  is given by **adjacency lists**. The vertices in  $V \setminus S$  are stored in a priority queue with  $\text{key} = \text{value of lightest edge to vertex in } S$ .

```

Prim( $G, w, r$ )
{
  for each  $u \in V$                                 initialize
  {
     $\text{key}[u] = +\infty$ ;
     $\text{color}[u] = W$ ;
  }
   $\text{key}[r] = 0$ ;                                    start at root
   $\text{pred}[r] = \text{NIL}$ ;
   $Q = \text{new PriQueue}(V)$ ;                          put vertices in  $Q$ 
  while( $Q$  is nonempty)                             until all vertices in MST
  {
     $u = Q.\text{extractMin}()$ ;                          lightest edge
    for each ( $v \in \text{adj}[u]$ )
    {
      if ( $(\text{color}[v] == W) \ \&\& \ (w[u, v] < \text{key}[v])$ )
         $\text{key}[v] = w[u, v]$ ;                          new lightest edge
         $Q.\text{decreaseKey}(v, \text{key}[v])$ ;
         $\text{pred}[v] = u$ ;
      }
    }
     $\text{color}[u] = B$ ;
  }
}

```

When the algorithm terminates,  $Q = \emptyset$  and the MST is

$$T = \{\{v, \text{pred}[v]\} : v \in V \setminus \{r\}\}.$$

The  $\text{pred}$  pointers define the MST as an inverted tree rooted at  $r$ .

## Example for Running Prim's Algorithm

| u       | a | b | c | d | e | f |
|---------|---|---|---|---|---|---|
| key[u]  |   |   |   |   |   |   |
| pred[u] |   |   |   |   |   |   |

## Analysis of Prim's Algorithm

Let  $n = |V|$  and  $e = |E|$ . The data structure PriQueue supports the following two operations: (See CLRS)

- $O(\log n)$  to **extract** each vertex from the queue.  
Done once for each vertex =  $O(n \log n)$ .
- $O(\log n)$  time to **decrease** the key value of neighboring vertex.  
Done at most once for each edge =  $O(e \log n)$ .

Total cost is then

$$O((n + e) \log n)$$

## Analysis of Prim's Algorithm – Continued

```

Prim(G, w, r) {
  for each (u in V)
  {
    key[u] = +infinity;
    color[u] = white;
  }
  key[r] = 0;
  pred[r] = nil;
  Q = new PriQueue(V);

  while (Q.nonempty())
  {
    u = Q.extractMin();
    for each (v in adj[u])
    {
      if ((color[v] == white) &
          (w(u,v) < key[v]))
      {
        key[v] = w(u, v);
        Q.decreaseKey(v, key[v]);
        pred[v] = u;
      }
    }
    color[u] = black;
  }
}

```

## Analysis of Prim's Algorithm – Continued

So the overall running time is

$$\begin{aligned} T(n, e) &= 3n + 2 + \sum_{u \in V} [O(\log n) + O(\deg(u) \log n)] \\ &= 3n + 2 + O \left[ (\log n) \sum_{u \in V} (1 + \deg(u)) \right] \\ &= 3n + 2 + O[(\log n)(n + 2e)] \\ &= O[(\log n)(n + 2e)] \\ &= O[(\log n)(n + e)] \\ &= O[(|V| + |E|) \log |V|]. \end{aligned}$$
