## File Access & Semantics of Sharing

- Overlapping / interleaving data access
  - When data is replicated in space to increase concurrency, coherency control is needed to keep the copies coherent
  - When data operations are spread out and interleaved in time, concurrency control is needed to prevent interference
  - Remote access no local data
  - Cache access small part kept locally
  - DL/UL access whole file is downloaded for local use, then uploaded

time / space	remote access	cache access	down/up load access
simple RW	no true	coherency	coherency
	sharing	control	control
transaction	concurrency control	concurrency control	concurrency control
session	not	not	ignore
	applicable	applicable	sharing

Fall 2005, Lecture 15

#### **Semantics of Sharing (cont.)**

- Alternatives for interleaving file operations:
  - Simple RW each read & write operation is an independent request
  - Transaction groups of reads and writes treated as an atomic action
  - Session sequence of transactions and simple RW operations, plus additional semantics
- Three different semantic models:
  - UNIX semantics result of a write goes immediately to the file, so reads always return the "latest" value
  - Transaction semantics writes go to local storage and go to file when and if the transaction commits
  - Session semantics similar, but writes go to the file when the session is closed

Fall 2005 | ecture 15

#### **Cache Location**

- No caching all files on server's disk
  - ✓ Simple, no local storage needed
  - **X** Expensive transfers
- Cache files in server's memory
  - ✓ Easy, transparent to clients
  - X Still involves a network access
- Cache files on client's local disk
  - ✔ Plenty of space, reliable
  - **X** Faster than network, slower than memory
- Cache files in client's memory
  - The usual solution (either in each process's address space, or in the kernel)
  - ✓ Fast, permits diskless workstations
  - X Data may be lost in a crash

# Cache Modification Policy

- Cache modification (writing) policy decides when a modified (dirty) cache block should be flushed to the server
- Write-through immediately flush the new value to server (& keep in cache)
  - ✓ No problems with consistency
  - ✓ Maximum reliability during crashes
  - ✗ Doesn't take advantage of caching during writes (only during reads)
- Write-back (delayed-write) flush the new value to server after some delay
  - ✓ Fast write need only hit the cache before the process continues
  - ✓ Can reduce disk writes since the process may repeatedly write the same location
  - ✗ Unreliable if machine crashes, unwritten data is lost

Fall 2005, Lecture 15

3

Fall 2005, Lecture 15

## **Cache Modification Policy (cont.)**

- Variations on write-back when are the new values flushed to the server?
  - Write-on-close flush new value to the server only when the file is closed
    - ✓ Can reduce disk writes, particularly when the file is open for a long time
    - ✗ Unreliable if machine crashes, unwritten data is lost
    - X May make the process wait on the file close
  - Write-periodically flush new value to the server at periodic intervals (maybe 30 seconds)
    - ✓ Can only lose writes in last period

**Cache Validation** 

- A client must decide whether or not a locally cached copy of data is consistent with the master copy
- Client-initiated validation:
  - Client initiates validity checks
  - Client contacts the server and asks if its copy is consistent with the server's copy
    - At every access, or
    - After a given interval, or
    - Only on file open
  - Server could enforce single-writer, multiple-reader semantics, but to do so
    - It would have to store client state (expensive)
    - Clients would have to specify access type (read / write) on open
  - ✗ High frequency of validity checks may mitigate the benefits of caching

Fall 2005, Lecture 15 6 Fall 2005, Lecture 15

# Cache Validation (cont.)

- Server-initiated validation:
  - Server records the parts of each file that each client caches
  - Server detects potential conflicts if two or more clients cache the same file
  - Concurrency control for handling conflicts:
    - Session semantics writes are only visible in sessions starting later (not to processes which have file open now)
      - When a client closes a file that it has modified, the server notifies the other clients that their cached copy is invalid, and they should discard it
        - » If another client has the file open, discard it when its session is over
    - UNIX semantics writes are immediately visible to others
      - Clients specify the type of access they want when they open a file, so if two clients want to write the same file for writing, that file is not cached
  - ★ Significant overhead at the server
    Fall 2005, Lecture 15

## Stateful vs. Stateless

- Stateful server server maintains state information for each client for each file
  - Connection-oriented (open file, read / write file, close file)
  - ✓ Enables server optimizations like readahead (prefetching) and file locking
  - X Difficult to recover state after a crash
- Stateless server server does not maintain state information for each client
  - Each request is self-contained (file, position, access)
    - Connectionless (open and close are implied)
  - ✓ If server crashes, client can simply keep retransmitting requests until it recovers
  - X No server optimizations like above
  - X File operations must be idempotent

Fall 2005, Lecture 15

7

#### **Caching in NFS**

#### ■ Traditional UNIX

- Caches file blocks, directories, and file attributes
- Uses read-ahead (prefetching), and delayed-write (flushes every 30 seconds)

## ■ NFS servers

- Same as in UNIX, except server's write operations perform write-through
  - Otherwise, failure of server might result in undetected loss of data by clients

#### NFS clients

- Caches results of read, write, getattr, lookup, and readdir operations
- Possible inconsistency problems
  - Writes by one client do not cause an immediate update of other clients' caches

Fall 2005, Lecture 15

## Caching in NFS (cont.)

## ■ NFS clients (cont.)

#### • File reads

- When a client caches one or more blocks from a file, it also caches a timestamp indicating the time when the file was last modified on the server
- Whenever a file is opened, and the server is contacted to fetch a new block from the file, a validation check is performed
  - Client requests last modification time from server, and compares that time to its cached timestamp
  - If modification time is more recent, all cached blocks from that file are invalidated
  - Blocks are assumed to valid for next 3 seconds (30 seconds for directories)

#### File writes

- When a cached page is modified, it is marked as dirty, and is flushed when the file is closed, or at the next periodic flush
- Now two sources of inconsistency: delay after validation, delay until flush

Fall 2005, Lecture 15

#### **Caching in Andrew**

- When a remote file is accessed, the server sends the entire file to the client
  - The entire file is then stored in a disk cache on the client computer
    - Cache is big enough to store several hundred files
- Implements session semantics
  - Files are cached when opened
  - Modified files are flushed to the server when they are closed
  - Writes may not be immediately visible to other processes
- When client caches a file, server records that fact it has a *callback* on the file
  - When a client modifies and closes a file, other clients lose their callback, and are notified by server that their copy is invalid

Fall 2005, Lecture 15

## **How Can Andrew Perform Well?**

- Most file accesses are to files that are infrequently updated, or are accessed by only a single user, so the cached copy will remain valid for a long time
- Local cache can be big maybe 100
   MB which is probably sufficient for one user's working set of files
- Typical UNIX workloads:
  - Files are small, most are less than 10kB
  - Read operations are 6 times more common than write operations
  - Sequential access is common, while random access is rare
  - Most files are read and written by only one user; if a file shared, usually only one user modifies it
  - Files are referenced in bursts
