

What is an Operating System? (Review)

- An *operating system* (OS) is the interface between the user and the hardware
 - It implements a virtual machine that is easier to program than bare hardware
 - An OS provides standard **services** (an interface) which are implemented on the hardware, including:
 - Processes, CPU scheduling, memory management, file system, networking
 - The OS **coordinates** multiple applications and users (multiple processes) in a fair and efficient manner
- ↪ The goal in OS development is to make the machine **convenient** to use (a software engineering problem) and **efficient** (a system and engineering problem)

Fall 2000, Lecture 02

History of Operating Systems

- Phase 0 — hardware is a very expensive experiment; no operating systems exist
 1. One user at console
 - One function at a time (computation, I/O, user think/response)
 - Program loaded via card deck
 - Libraries of device drivers (for I/O)
 - User debugs at console
 2. Simple batch processing: load program, run, print results, dump, repeat
 - User gives program (cards or tape) to the operator, who schedules the jobs
 - *Resident monitor* automatically loads, runs, dumps user jobs
 - Requires memory management (relocation) and protection
 - More efficient use of hardware, but debugging is more difficult (from dumps)
- Phase 1 — hardware is expensive, humans are cheap
 2. Simple batch processing: load program, run, print results, dump, repeat

2

Fall 2000, Lecture 02

History of Operating Systems (cont.)

- Phase 1 — hardware is expensive, humans are cheap
 3. Overlapped CPU & I/O operations
 - First: buffer slow I/O onto fast tape drives connected to CPU, replicate I/O devices
 - Later: *spool* data to disk
 4. Multiprogrammed batch systems
 - Multiple jobs are on the disk, waiting to run
 - *Multiprogramming* — run **several** programs at the “same” time
 - Pick some jobs to run (*scheduling*), and put them in memory (*memory management*)
 - Run one job; when it waits on something (tape to be mounted, key to be pressed), switch to another job in memory
 - First big failures:
 - MULTICS announced in 1963, not released until 1969
 - IBM’s OS/360 released with 1000 known bugs
 - OS design should be a science, not an art

3

Fall 2000, Lecture 02

History of Operating Systems (cont.)

- Phase 2 — hardware is less expensive than before, humans are expensive
 5. Interactive *timesharing*
 - Lots of cheap terminals, one computer
 - All users interact with system at once
 - Debugging is much easier
 - Disks are cheap, so put programs and data online
 - 1 punch card = 100 bytes
 - 1MB = 10K cards
 - OS/360 was several feet of cards
 - New problems:
 - Need *preemptive scheduling* to maintain adequate *response time*
 - Need to avoid *thrashing* (swapping programs in and out of memory too often)
 - Need to provide adequate security measures
 - Success: UNIX developed at Bell Labs so a couple of computer nerds (Thompson, Ritchie) could play Star Trek on an unused PDP-7 minicomputer

4

Fall 2000, Lecture 02

History of Operating Systems (cont.)

- Phase 3 — hardware is very cheap, humans are expensive
- 6. Personal computing
 - CPUs are cheap enough to put one in each terminal, yet powerful enough to be useful
 - Computers for the masses!
 - Return to simplicity; make OS simpler by getting rid of support for multiprogramming, concurrency, and protection

■ Modern operating systems are:

- Enormous
 - Small OS = 100K lines of code
 - Big OS = 10M lines
- Complex (100-1000 person year of work)
- Poorly understood (outlives its creators, too large for one person to comprehend)

5

Fall 2000, Lecture 02

History Lessons

- None of these operating systems were particularly bad; each depended on tradeoffs made at that point in time
 - Technology changes drive OS changes
- Since 1953, there has been about 9 orders of magnitude of change in almost every computer system component
 - Unprecedented! In past 200 years, gone from horseback (10 mph) to Concorde (1000 mph), only 2 orders of magnitude
- Changes in “typical” academic computer:

	<u>1981</u>	<u>1996</u>
MIPS	1	400
price / MIPS	\$100,000	\$50
memory	128 KByte	64 MByte
disk	10 MByte	4 GByte
network	9600 bit/sec	155 Mb/s
address bits	16	64

Modern OS Functionality (Review)

- Concurrency
 - Multiple processes active at once
 - Processes can communicate
 - Processes may require mutually-exclusive access to some resource
 - CPU scheduling, resource management
- Memory management — allocate memory to processes, move processes between disk and memory
- File system — allocate space for storage of programs and data on disk
- Networks and distributed computing — allow computers to work together
- Security & protection

7

Fall 2000, Lecture 02

More Recent Developments

- Parallel operating systems
 - Shared memory, shared clock
 - Large number of tightly-coupled processors
 - Appearance of single operating system
- Distributed operating systems
 - No shared memory, no shared clock
 - Small number of loosely-coupled processors
 - Appearance of single operating system is ideal goal, but not realized in practice
 - May try to simulate a shared memory
- Real-time operating systems
 - Meet hard / soft real-time constraints on processing of data
