# Topics in Memory Management (Review)

- Uniprogrammed operating systems
  - Assembling, linking, loading
  - Static memory allocation
  - Dynamic memory allocation
    - Stacks, heaps
    - Managing the free list, memory reclamation
- Multiprogrammed operating systems
  - Includes most of the above topics
  - Static relocation
  - Dynamic relocation
    - Virtual vs. physical address
    - Partitioning (and compaction)
    - Segmentation
    - Paging
  - Swapping
  - Demand paging

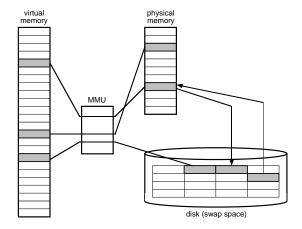

Fall 2000, Lecture 27

#### **Memory Management So Far**

- An application's view of memory is its virtual address space
- OS's view of memory is the physical address space
- A MMU (hardware) is used to implement segmentation, paging, or a combination of the two, by providing address translation
- Limitation until now <u>all</u> segments / pages of a process must be in main (physical) memory for it to run
- Insight at a given time, we probably only need to access some small subset of process's virtual memory
  - Load pages / segments on demand

Fall 2000, Lecture 27

## **Demand Paging (Virtual Memory)**

- At a given time, a virtual memory page will be stored either:
  - In a frame in physical memory
  - On disk (backing store, or swap space)
- A process can run with only part of its virtual address space in main memory
  - Provide illusion of almost infinite memory

### **Starting a New Process**

- Processes are started with 0 or more of their virtual pages in physical memory, and the rest on the disk
- Page selection <u>when</u> are new pages brought into physical memory?
  - Prepaging pre-load enough to get started: code, static data, one stack page (DEC ULTRIX)
  - Demand paging start with 0 pages, load each page on demand (when a page fault occurs) (most common approach)
    - Disadvantage: many (slow) page faults when program starts running
- Demand paging works due to the principle of *locality of reference* 
  - Knuth estimated that 90% of a program's time is spent in 10% of the code

Fall 2000, Lecture 27 4 Fall 2000, Lecture 27

#### **Page Faults**

- An attempts to access a page that's not in physical memory causes a page fault
  - Page table must include a present bit (sometimes called valid bit) for each page
  - An attempt to access a page without the present bit set results in a page fault, an exception which causes a trap to the OS
  - When a page fault occurs:
    - OS must *page in* the page bring it from disk into a free frame in physical memory
    - OS must update page table & present bit
    - Faulting process continues execution
- Unlike interrupts, a page fault can occur any time there's a memory reference
  - Even in the middle of an instruction! (how? and why not with interrupts??)
  - However, handling the page fault must be invisible to the process that caused it

Fall 2000, Lecture 27

## **Performance of Demand Paging**

■ Effective access time for demand-paged memory can be computed as:

$$eacc = (1-p)(macc) + (p)(pfault)$$

#### where:

p = probability that page fault will occurmacc = memory access timepfault = time needed to service page fault

■ With typical numbers:

eacc = 
$$(1-p)(100) + (p)(25,000,000)$$
  
=  $100 + (p)(24,999,800)$ 

- If p is 1 in 1000, eacc = 25,099 ns (250 times slower!)
- To keep overhead under 10%, 110 > 100 + (p)(24,999,800)
  - p must be less than 0.0000004
  - Less than 1 in 2,5000,000 memory accesses must page fault!

#### **Handling Page Faults**

- The page fault handler must be able to recover enough of the machine state (at the time of the fault) to continue executing the program
- The PC is usually incremented at the beginning of the instruction cycle
  - If OS / hardware doesn't do anything special, faulting process will execute the next instruction (skipping faulting one)
- With hardware support:
  - Test for faults before executing instruction (IBM 370)
  - Instruction completion continue where you left off (Intel 386…)
  - Restart instruction, undoing (if necessary) whatever the instruction has already done (PDP-11, MIPS R3000, DEC Alpha, most modern architectures)

Fall 2000, Lecture 27

#### **Page Replacement**

- When the OS needs a frame to allocate to a process, and all frames are busy, it must evict (copy to backing store) a page from its frame to make room in memory
  - Reduce overhead by having CPU set a modified / dirty bit to indicate that a page has been modified
    - Only copy data back to disk for dirty pages
    - For non-dirty pages, just update the page table to refer to copy on disk
- Which page to we choose to replace? Some page replacement policies:
  - Random
    - Pick any page to evict
  - FIFO
    - Evict the page that has been in memory the longest (use a queue to keep track)
    - Idea is to give all pages "fair" (equal) use of memory
