

The Producer-Consumer Problem

- One process is a producer of information; another is a consumer of that information
- Processes communicate through a bounded (fixed-size) circular buffer

```
var buffer: array[0..n-1] of items; /* circular array */
in = 0
out = 0
```

```
/* producer */
repeat forever
...
produce item nextp
...
while (in+1 mod n == out)
do nothing
buffer[in] = nextp
in = in+1 mod n
end repeat

/* consumer */
repeat forever
while (in == out)
do nothing
nextc = buffer[out]
out = out+1 mod n
...
consume item nextc
...
end repeat
```

Message Passing using Send & Receive

- Blocking send:
 - `send(destination-process, message)`
 - Sends a message to another process, then *blocks* (i.e., gets suspended by OS) until message is received
- Blocking receive:
 - `receive(source-process, message)`
 - Blocks until a message is received (may be minutes, hours, ...)

- Producer-Consumer problem:

```
/* producer */
repeat forever
...
produce item nextp
...
send(consumer, nextp)
end repeat

/* consumer */
repeat forever
receive(producer, nextc)
...
consume item nextc
...
end repeat
```

Direct vs. Indirect Communication

- Direct communication — explicitly name the process you're communicating with
 - `send(destination-process, message)`
 - `receive(source-process, message)`
 - Variation: receiver may be able to use a "wildcard" to receive from any source
 - Receiver can not distinguish between multiple "types" of messages from sender
- Indirect communication — communicate using mailboxes (owned by receiver)
 - `send(mailbox, message)`
 - `receive(mailbox, message)`
 - Variation: ... "wildcard" to receive from any source into that mailbox
 - Receiver can distinguish between multiple "types" of messages from sender
 - Some systems use "tags" instead of mailboxes

Buffering

- Link may be able to temporarily queue some messages during communication
- Zero capacity: (queue of length 0)
 - Blocking communication
 - Sender must wait until receiver receives the message — this synchronization to exchange data is called a *rendezvous*
- Bounded capacity: (queue of length n)
 - If receiver's queue is not full, new message is put on queue, and sender can continue executing immediately
 - If queue is full, sender must block until space is available in the queue
- Unbounded capacity: (infinite queue)
 - Non-blocking communication
 - Sender can always continue

Client / Server Model using Message Passing

■ Client / server model

- **Server** = process (or collection of processes) that provides a *service*
 - Example: name service, file service
- **Client** — process that uses the service
- Request / reply protocol:
 - Client sends **request** message to server, asking it to perform some service
 - Server performs service, sends **reply** message containing results or error code

Remote Procedure Call (RPC)

■ RPC mechanism:

- Hides message-passing I/O from the programmer
- Looks (almost) like a procedure call — but client invokes a procedure on a server

■ RPC invocation (high-level view):

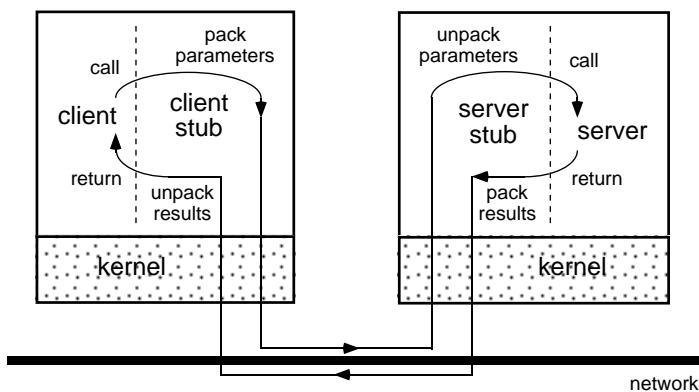

- Calling process (client) is suspended
- Parameters of procedure are passed across network to called process (server)
- Server executes procedure
- Return parameters are sent back across network
- Calling process resumes

- Invented by Birrell & Nelson at Xerox PARC, described in February 1984 *ACM Transactions on Computer Systems*

6

Fall 2001, Lecture 07

Client / Server Model using Remote Procedure Calls (RPCs)

- Each RPC invocation by a client process calls a *client stub*, which builds a message and sends it to a *server stub*
- The server stub uses the message to generate a local procedure call to the server
- If the local procedure call returns a value, the server stub builds a message and sends it to the client stub, which receives it and returns the result(s) to the client

7

Fall 2001, Lecture 07

RPC Invocation (More Detailed)

1. Client procedure calls the client stub
2. Client stub packs parameters into message and traps to the kernel
3. Kernel sends message to remote kernel
4. Remote kernel gives message to server stub
5. Server stub unpacks parameters and calls server
6. Server executes procedure and returns results to server stub
7. Server stub packs result(s) in message and traps to kernel
8. Remote kernel sends message to local kernel
9. Local kernel gives message to client stub
10. Client stub unpacks result(s) and returns them to client
