## $r$ -Domination and $p$ -Center

---

# $r$ -Domination Problem

## (Connected) $r$ -Domination Problem

For a given graph  $G = (V, E)$  and given function  $r: V \rightarrow \mathbb{N}$ , determine a (connected) vertex set  $D$  with minimum cardinality such that, for each vertex  $v$ ,  $d(v, D) \leq r(v)$ .

Optimal  $r$ -domination.

# $p$ -Center Problem

## (Connected) $p$ -Center Problem

For a given graph  $G = (V, E)$  and given integer  $p$ , determine a (connected) vertex set  $D$  with  $|D| \leq p$  such that  $\max_{v \in V} d(v, D)$  is minimal.

Optimal connected 3-center.

# $r$ -Domination vs. $p$ -Center

Two versions of the same problem.

## $r$ -Domination

- ▶ Given: Maximal distance.
- ▶ Find: Best cardinality.

## $p$ -Center

- ▶ Given: Maximal cardinality.
- ▶ Find: Lowest maximum distance.

An algorithm for one problem gives an algorithm for the other problem with low computational overhead.

# Approximation for $r$ -Domination

## Theorem

[Chlebík, Chlebíková 2008]

Under reasonable assumptions, the  $r$ -Domination problem cannot be approximated within a factor of  $(1 - \varepsilon) \ln n$  in polynomial time. (Even for very restricted graphs).

## Our Approach

- ▶ Do not approximate cardinality, approximate range of  $r$ .
- ▶ Goal: Find  $(r + \phi)$ -dominating set not larger than the optimal set.
- ▶ An  $(r + \phi)$ -dominating set gives an  $+\phi$ -approximation for the  $p$ -Center problem.

## Existing Result

- ▶  $(r + 2\delta)$ -dominating set in polynomial time for  $\delta$ -hyperbolic graphs [Chepoi, Estellon 2007]

---

## Layering Partition

---

# Layering Partition

## Layering Partition

[Brandstädt et al. 1999; Chepoi, Dragan 2000]

- ▶ Distance layers for a given vertex  $s$
- ▶ Partition each layer:  $u$  and  $v$  are in the same cluster if they are connected by a path only using the same or upper layers
- ▶ Computable in linear time

$\Delta$  denotes max. distance (in  $G$ ) of two vertices in a cluster.

# Algorithm

---

# General Approach

## Idea

- Compute layering partition  $\mathcal{T}$  for graph  $G$ .

# General Approach

## Idea

- ▶ Compute layering partition  $\mathcal{T}$  for graph  $G$ .
- ▶ Solve problem for  $\mathcal{T}$ .

# General Approach

## Idea

- ▶ Compute layering partition  $\mathcal{T}$  for graph  $G$ .
- ▶ Solve problem for  $\mathcal{T}$ .
- ▶ Use solution for  $\mathcal{T}$  to compute solution for underlying graph  $G$ .

## $r$ -Domination (non-connected)

### Solving $r$ -Domination for $\mathcal{T}$

- ▶ Set  $r(C) = \min_{v \in C} r(v)$  for each cluster  $C$  of  $\mathcal{T}$ .
- ▶ Find minimum  $r$ -dominating set  $\mathcal{S}$  for  $\mathcal{T}$ .

## $r$ -Domination (non-connected)

### Compute solution for $G$

- ▶ For each cluster  $C \in \mathcal{S}$ , pick a vertex  $v \in C$  and add  $v$  into a set  $D$ .
- ▶  $D$  is an  $(r + \Delta)$ -dominating set for  $G$ .
- ▶ Total runtime: linear

# Connected $r$ -Domination

## Solving Connected $r$ -Domination for $\mathcal{T}$

- ▶ Set  $r(C) = \min_{v \in C} r(v)$  for each cluster  $C$  of  $\mathcal{T}$ .
- ▶ Find minimum connected  $r$ -dominating set (i. e., a subtree)  $T_r$  for  $\mathcal{T}$ .
- ▶ Useful:  $|T_r| \leq |D_r|$   
( $D_r$  is *unknown* optimal con.  $r$ -dom. set for  $G$ )

# Connected $r$ -Domination

## Compute solution for $G$ ?

- ▶ For each cluster  $C \in \mathcal{S}$ , pick a vertex  $v \in C$  and add  $v$  into a set  $D$ .

## Problems

- ▶ How to ensure connectedness?
- ▶ How do we ensure cardinality constraints?

## Idea

- ▶ Construct  $(r + \delta)$ -dominating subtree  $T_\delta$  of  $\mathcal{T}$  for some  $\delta \in \mathbb{N}$ .
- ▶ Construct small enough vertex set  $S_\delta$  of  $G$  intersecting all clusters of  $T_\delta$
- ▶ Try different values for  $\delta$  until  $|S_\delta| \leq |T_r|$  and, thus,  $|S_\delta| \leq |D_r|$ .

# Constructing $S_\delta$ – Set of Shortest Paths $\mathcal{P}$

Construct  $T_\delta$

# Constructing $S_\delta$ – Set of Shortest Paths $\mathcal{P}$

Pick a vertex  $v$  in an unmarked leaf  $C$  (excluding the root) of  $T_\delta$

# Constructing $S_\delta$ – Set of Shortest Paths $\mathcal{P}$

Find the highest unmarked ancestor  $C'$  of  $C$  and a shortest path  $P$  from  $v$  to a vertex  $v' \in C'$ .

Add  $P$  to a set of paths  $\mathcal{P}$ .

Mark all clusters intersected by  $P$ .

## Constructing $S_\delta$ – Set of Shortest Paths $\mathcal{P}$

Repeat for each leaf of  $T_\delta$ .

## Constructing $S_\delta$ – Connect Paths in $\mathcal{P}$

Run BFS starting simultaneously from all  $P \in \mathcal{P}$ . Gives a partition  $\mathcal{V} = \{V_1, V_2, \dots\}$  of  $V$ .

Connect paths in  $\mathcal{P}$  similar to KRUSKAL's MST algorithm based on edges  $uv$  with  $u \in V_i$  and  $v \in V_j$ .

# Connected $r$ -Domination – Finding best $\delta$

## One-Sided Binary Search

- ▶ Start with  $\delta = 0$ . Then,  $\delta = 1, \delta = 2, \delta = 4, \delta = 8, \dots$  until  $|S_\delta| \leq |T_r|$ .
- ▶ Next, classical binary search between last values of  $\delta$ .
- ▶ If  $|S_\delta| \leq |T_r|$ , decrease  $\delta$ .  
Otherwise, increase  $\delta$ .

## Result

- ▶ Connected  $(r + \Delta + \delta)$ -dominating set  $S_\delta$  with  $\delta \leq \Delta$  (i. e.,  $(r + 2\Delta)$ -dom. set)
- ▶  $+2\Delta$ -Approximation for Connected  $p$ -Center problem
- ▶ Runtime:  $O(m \alpha(n) \log \Delta)$

---

## Using Tree-Decompositions

---

# Tree-Decomposition of a Graph

A family  $\mathcal{T} = \{B_1, B_2, \dots, B_k\}$  of subsets of  $V$  (called bags) which form a tree such that

- ▶ each vertex is in a bag,
- ▶ each edge is in a bag, and
- ▶ the bags containing a vertex induce a subtree.

# Tree-Breadth and Tree-Length

**Tree-Breadth** ( $\text{tb}(G) \leq \rho$ )

- ▶ Each bag  $B$  has a center  $v$  such that  $d(u, v) \leq \rho$  for each vertex  $u \in B$ .

**Tree-Length** ( $\text{tl}(G) \leq \lambda$ )

- ▶ Each bag  $B$  has a diameter at most  $\lambda$ , i. e., for all  $u, v \in B$ ,  $d(u, v) \leq \lambda$ .

# Approximation for $r$ -Domination

## Idea

- ▶ Find smallest subtree  $\mathcal{T}$  of decomposition that intersects all  $r$ -disks.
- ▶ Pick center  $c$  of leaf of  $\mathcal{T}$  and add it to set.
- ▶ Removes all  $r$ -disks in distance  $\rho$  to  $c$ . Repeat.

# Approximation for Connected $r$ -Domination

## Idea

- ▶ Find smallest subtree  $\mathcal{T}$  of decomposition that intersects all  $r$ -disks.
- ▶ Pick center  $c$  of leaf of  $\mathcal{T}$  and add it to set.
- ▶ Find small (enough) set connecting all bags.

# Using Tree-Decompositions – Results

Assumption: Decomposition is given and  $\rho, \lambda$  are known.

## **$r$ -Domination**

- ▶  $(r + \rho)$  in  $O(nm)$  time

## **Connected $r$ -Domination**

- ▶  $(r + 3\lambda)$  in  $O(nm)$  time
- ▶  $(r + 5\rho)$  in  $O(nm)$  time

## **Open Question**

- ▶ Same result possible without known tree decomposition?

---

## Implications for $p$ -Center Problem

---

# Implications for $p$ -Center Problem

## Theorem

If an  $O(T(G))$  time algorithm computing a (connected)  $(r + \phi)$  dominating set is given, one can compute a  $+\phi$ -approximation for the (connected)  $p$ -Center problem in  $O(T(G) \log n)$  time.

Approach	Approx.	Time
Layering Partition	$+2\Delta$	$O(m \alpha(n) \log \Delta \log n)$
Tree-Decomposition	$+\min(5\rho, 3\lambda)$	$O(nm \log n)$

---

Thank you!
